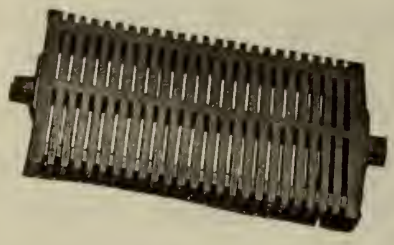
CYCLONE GRATES



Don't Waste Your Fuel

The 90 per cent. under-draught and 60 per cent. air space of Cyclone Grates mean practically no clinkers—even when you burn screenings and other low grade fuels.

Their jarring, shaking movement sifts **all** the ashes through; and **all** the good fuel remains.

You **need** Cyclone Grates, and if you need a thing you pay for it whether you buy it or not. Our 30 days' free trial offer will convince you. Why not write to-day for full particulars?

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Jenkins Valves

Made *for* Maximum Service

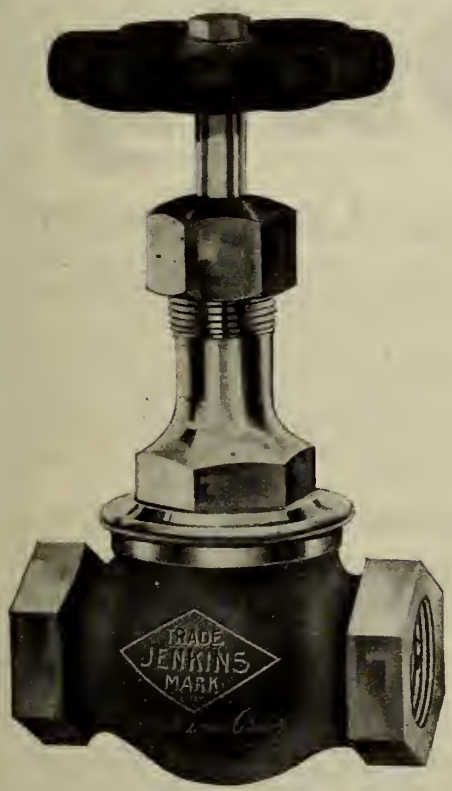

Fig. 105
JENKINS BRASS GLOBE VALVE
Suitable for 175 lbs. Working Steam Pressure or 250 lbs. Working Water Pressure.

The dependability and longevity of genuine Jenkins Valves are due to the fact that every valve in every type is made for the Maximum Service.

The man who knows valves and valve requirements installs Jenkins. Their trouble-free record in every branch of Service is a guarantee of satisfaction even under unusually severe conditions.

Jenkins Valves for every service are obtainable at supply houses everywhere. The line is very complete, including valves of brass, iron and cast steel for all requirements of power plants, industrial establishments, plumbing and heating service, etc. When buying look for the name "Jenkins" within a Diamond Mark on the body of the valve. It's there for your protection.

Catalog No. 8 describes the entire Jenkins line. Send for free copy.

High-Duty

—The Short Cut to Low Cost Power

HAVE you a definite conception of just what "high-duty" means as applied to the Jones "A-C" (Automatic-Cleaning) Stoker?

High-Duty Implies first of all, ability to meet any conceivable load condition, whether a steadily maintained overload or a widely fluctuating load where enormous peaks must be met almost momentarily. The automatic-control of fuel and air, and individual control of retorts embodied in the Jones "A-C," makes this a certain result.

High-Duty Means not merely heavy overload capacity, but ability to maintain overloads continuously without shutdowns and with minimum maintenance costs. The automatic-cleaning ("A-C") feature, the absence of clinker on side and bridge walls, and the rugged simplicity, making repairs almost negligible, insures *continuous operation at all loads.*

High-Duty Signifies not alone maintained overload capacity, but ability to fulfill this condition while burning every and any grade of fuel. The underfeed principle (a *Jones* principle) as perfected in the Jones "A-C," adapts this stoker to coals of every firing characteristic.

High-Duty Summarizes the features that have given the Jones "A-C" a wider range of utility recorded in greater return on stoker investment in plants of every size. The new "A-C" catalog goes into detail.

The services of an old-established and newly re-organized and expanded engineering organization—formerly the Jones Under-Feed Stoker Company, Limited, and now the Under-Feed Stoker Co. of Canada, Limited—are at your disposal. Request (without obligating yourself in any way) the new "A-C" catalog.

Sturtevant
(TRADE MARK)
TURBINES

Anticipate New Demands for Economy

Demands made to-day of turbines designed for driving fans, blowers, generators and pumps are more exacting than ever before, consequently turbines built to meet requirements of the past, cannot compete with those built for modern conditions.

Sturtevant Type 10 Turbine

anticipates these ever changing requirements and gives economical and dependable service regardless of the range in load. Continuous operation is assured with minimum steam consumption.

The nozzles and reverse buckets are features worthy of mention when the advantages of Sturtevant Turbines are considered. By simply closing a hand valve each individual nozzle can be cut out of service. This makes it possible for light loads to be carried without shutting off the main steam supply. The buckets are made from tobin bronze, carefully fitted and polished to reduce steam friction. Milled into the rim by our own patented process.

The emergency valve assures reliability. It is connected to an emergency governor and when a predetermined speed is exceeded, closes instantly and automatically. This turbine has been twelve years on the market. In horsepowers from one to five hundred.

Our engineers solicit your correspondence in regard to applying Sturtevant Turbines to your particular needs.

Send for catalog 256N for detailed description of construction.

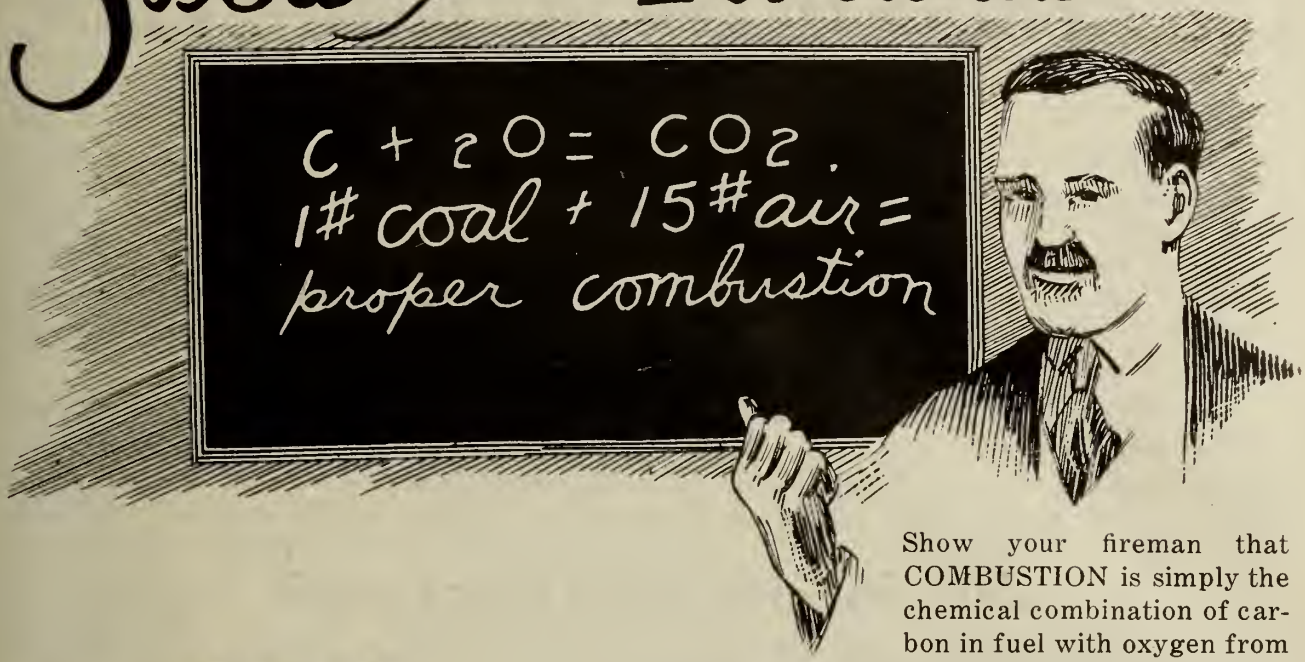
Show your Fireman



Show your fireman that COMBUSTION is simply the chemical combination of carbon in fuel with oxygen from the air; that perfect combustion consists in bringing together the proper proportion of each, and that too much draft means a lot of extra air to be heated up to 500° or more with heat that might just as well produce steam.

Hays Draft Gage

Then equip each boiler with

HAYS DRAFT GAGE and HAYS AUTOMATIC CO_2 and DRAFT RECORDER

and both you and your fireman will know what is happening in the boiler room. Your fireman will be able to make the proper adjustments to better his efficiency. He will not have to guess. He will know when, how and why to act. Naturally he will take a new interest in his work—if you will but do your part.

Back of all Hays Apparatus is "Hays Service" which may be worth as much as the actual equipment. This service includes expert inspection of your plant and advice and instructions as to just what you need and how to install and derive the greatest benefit from it.

Carrying On By Marking Time

By J. K. Munro

HAY foot—straw foot—left foot—right foot—and never getting anywhere! That's J. K. Munro's view of the Parliament at Ottawa during March. Crerar and Lapointe are the only men who have really said anything, in "J. K.'s" opinion. After a survey of the Dominion Mr. Munro prophesies that there will be a Farmer Government, sure, in 1922—and probably supported by several French-Canadians.

And the Budget—"it is not likely," says Canada's leading political pundit, "that it will be a very sweeping document. It will likely provide for a sales tax of about one per cent, to make up the hundred million by which the estimates exceed the revenue, and the excess profits tax will likely be wiped out. That's about all."

John Barleycorn and Jack Canuck

It's a hard question for the man-on-the-street to answer, How Dry is Canada? But Charles Christopher Jenkins has studied the question from all angles, and you will find his article extraordinarily informative and—in the light of Ontario's vote April 18—very timely.

"For Sale For a Song."
By Agnes C. Laut.

The question whether Oriental labor will solve some of our problems is here discussed.

"From Ontario to Tin Pan Alley."
By Geoffrey O'Hara.

Accuracy!

When we first started to make gauges away back in 1851, we selected the word **Accuracy** as our manufacturing slogan. Unwavering adherence to that policy is responsible to-day for the universal reputation for reliable performance that attaches to American gauges.

When you install an American Gauge you know that it will prove dependable because you know that it is conscientiously as well as scientifically built.

American Gauges respond with infallible accuracy to every pressure variation.

At every point, ACCURACY. And along with Accuracy, the durability that assures long service.

Our Catalog No. 70 gives other interesting facts that you ought to know. Write for it to-day.

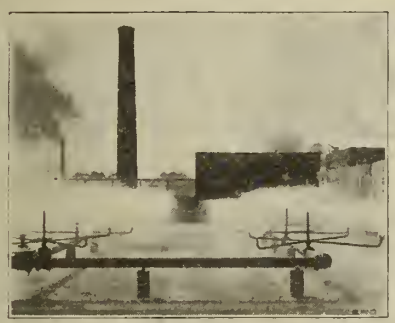
"SPRA-RITE"



Iowa Railway & Light Co.,
Marshalltown.

Central Illinois Public Service Co.,
Harrisburg, Ill. Capacity 10,000
G.P.M.

SPRA-RITE
Two-Vane Nozzle

The function of the SPRA-RITE is to discharge fine spray of equal density throughout its entire cross section.

Cooling Systems for Cooling Condenser Water

Meet Modern Conditions—Cut the Costs

COOLING systems representative of the best practice a decade ago are virtually obsolete now. "The SPRA-RITE" System fills the bill to-day, meeting as it does all the requirements in the shape of capacity, flexibility and cooling efficiency.

SPRA-RITE Cooling Systems have proved their efficiency. Tests made on the coal pile by means of the increased vacuum obtained prove that many systems have made a 50 to 100 per cent. return on the original investment in a year's time. Frequently a reduction in insurance rates is also obtained by reason of ample water supply close at hand for use by fire pumps.

For steam condensing equipment, SPRA - RITE Cooling Systems represent the highest standard of efficiency, but a spray cooling system will show its highest efficiency only when equipped with SPRA-RITE Nozzles, which were primarily designed for this application.

Owing to the rapid adoption of the Steam Turbine and Steam Condensation Equipment water cooling has become a factor of great importance to the manufacturer.

Whitman & Barnes Mfg. Co.,
West Pullman, Ill.

For this reason plant sites within easy reach of natural bodies of water for condensation are in demand. But such sites are not always available. It is then necessary to install Spray Cooling Ponds for cooling the condenser water so that the available supply can be used over and over again.

Spray ponds vary in construction. Concrete ponds are the most popular, but natural ponds, earthen basins and roofs may be utilized. We will recommend and furnish plans to suit your conditions.

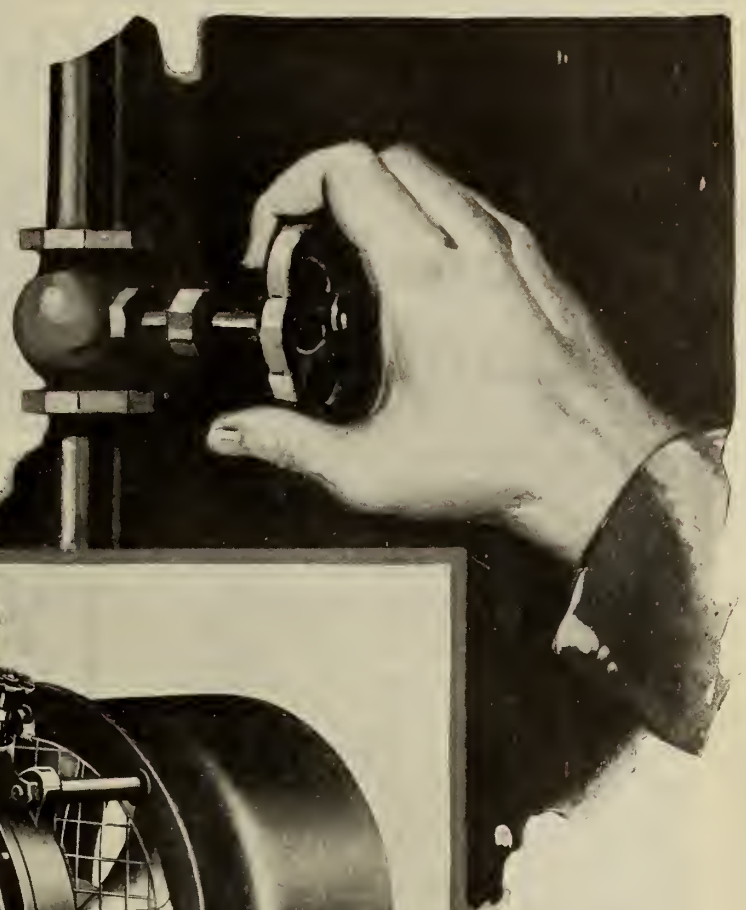
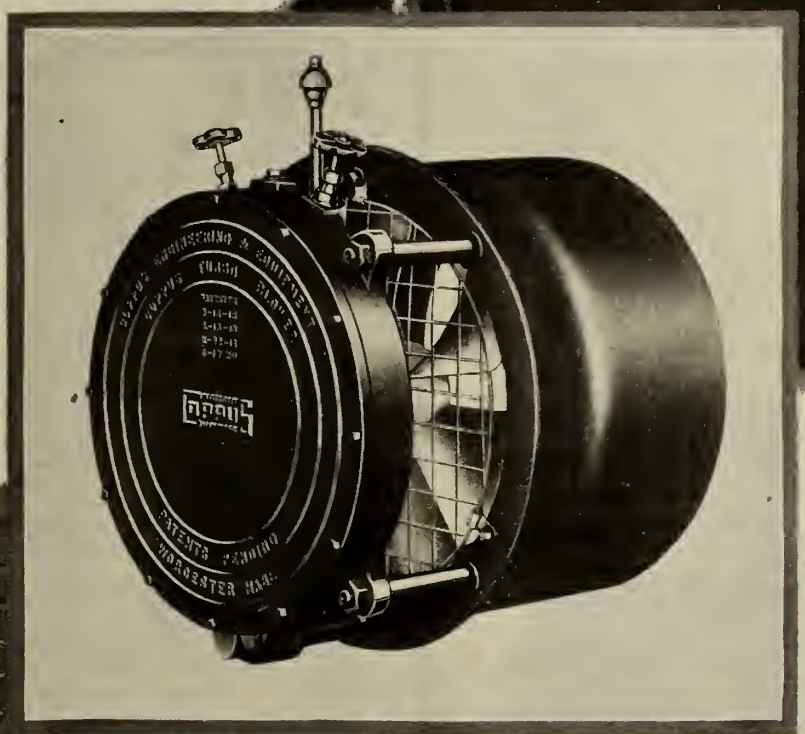
Turbo Blower will give you Valve-Control of your fire



ONCE unheard of — to-day standard practice in our most efficient boiler plants—*valve control of your fires.*

A turn of the valve gives an immediate "pick-up" of your fires. More steam in a hurry—and; mind you, the cheapest and poorest grades of coal can be successfully burned.



It is almost as easy to install a Coppus Turbo Blower under your boilers as it is to put an electric fan in your office. Merely cut a hole in the boiler setting—mason in the casing—make the simple steam connection, and it's done. Then you have valve-control of your fire—as easy as regulating the flame of a gas jet.

Coppus Turbo Blowers are standard equipment in efficiently operated boiler plants.

Our booklet contains interesting blower data. Ask for it.

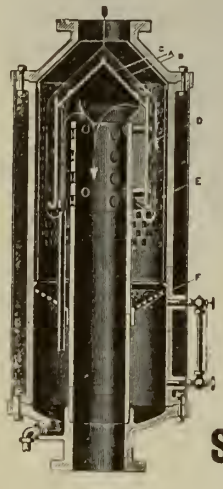
III IMPORTANT THINGS
TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

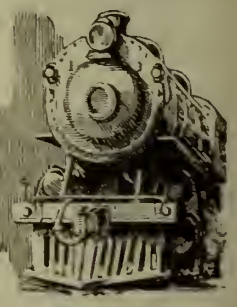
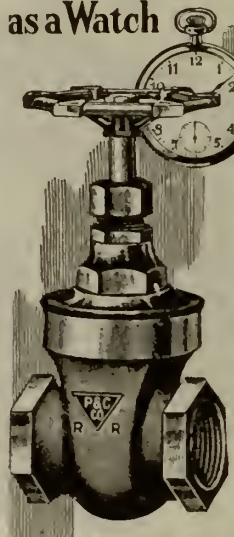
STRONG as a Locomotive
FINE as a Watch





For sheer physical strength, plus delicate adjustment, no valve can compare with a Pratt & Cady.

Old-time users of Pratt & Cady Valves who have found valves in their plants as good as the day they were installed, thirty or forty years before, marvel at their durability.

But when you consider their massive construction, the superior grades of metal used, the painstaking labor expended on their construction, and the renewable disc (or renewable seat) feature which practically makes a new valve out of a Pratt & Cady Valve that has seen long service, there is every reason why they should last indefinitely.

Write for our Valve Catalog showing Globe and Gate Valves for every type of service.

Donner Steel Co.

Diamond Soot Blowers Mean Greater Profits

WHEREVER industry uses power generated by steam, in large quantities, there you will find Diamond Soot Blowers.

This is particularly true in the steel industry, where in addition to the incentive of fuel saving resulting from the maintenance of clean heating surfaces in the boilers, there is the further important consideration of keeping machinery in all departments operating at full capacity,—a result generally possible only when boilers are operating at highest ratings and efficiencies.

In addition to the economies resulting from their general application—economies such as a fuel saving of 4 to 8 per cent., and an increase in boiler efficiency of 3 to 4 per cent.—Diamond Soot Blowers are an especial source of dividends in the steel industry because of their adaptability to the cleaning of boilers fired by blast furnace gas and waste heat from open hearth furnaces.

Among a few of the several hundred iron and steel plants which are increasing dividends with Diamond Soot Blowers, the following are typical :

Andrews Steel Company	Carnegie Steel Company
Lukens Steel Company	Bethlehem Steel Company
American Rolling Mill Company	Trumbull Steel Company
Illinois Steel Company	Atlantic Steel Company
Donner Steel Company	American Steel Company
Wisconsin Steel Company	Ohio Forge Company
Pittsburgh Steel Company	Midvale Steel Company

If your boilers are not equipped with Diamond Soot Blowers you can profitably follow the example of the big steel mills.

SOOT BLOWERS - SAVE 4 to 8% FUEL

Extravagance Must Stop!

THE COPES Boiler Feed REGULATOR

is a vital organ in the system which draws the latent energy out of the coal pile and delivers it at the bus bar or the main drive shaft.

Without the Copes Boiler Feed Regulator none of the other organs can perform its function properly. Stokers, feed water heaters, water softeners, and the boilers themselves cannot do their best without proper feed water regulation. The legibility of steam and water flow records, pressure and temperature charts, all depend more or less on scientific feed water regulation.

For complete information about COPES BOILER FEED REGULATORS, ask for Bulletin D.

Temperature Efficiency

Indicating, Recording, Controlling

A book that should have a place in every industrial library. Authoritative. 1,000 illustrations. Compiled by engineers. Serves also as catalogue for Tycos Temperature instruments.

Sent postpaid, without obligation, when requested by executives or engineers

Taylor Instrument Companies
ROCHESTER, N.Y.
Canadian Branch: 110-112 CHURCH ST., TORONTO.
There's a Tycos or Taylor Temperature Instrument for every purpose

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract. Readers are requested to advise the publishers regarding any equipment that they are buying and that is not listed.

HEAD OFFICE FOR CANADA - COLLEGE ST. (ST. HENRY), MONTREAL
TORONTO OFFICE, TRADERS BANK BUILDING

Ten hours! More than a day's labor! Think of the cost in dollars!

Such was the result of a test between the flexible type of hack saw and an all-hard blade.

Both were designed to cut the same material! Both were carefully run to deliver the utmost service, but the all-hard blade demonstrated from the start that it cut costs by cutting quicker. On power sawing, where weight is needed to make the teeth of a blade "bite" into the stock, the soft-back saw is not practical. Because of its flexibility, pressure makes it "buckle" Without this weight the cost per cut is too high.

For economical power sawing the proper blade for the particular kind of material to be cut is indicated by the Starrett Hacksaw Chart. It will be mailed to you, free.

HEPBURN
PATENT
PUMPS

IF you take a pride in the equipment of your Power House, you will want a reliable, high-class pump. The "Hepburn" is a pump of which you can be justly proud.

The vertical outside packed ram pump, illustrated, is specially designed to handle high temperature water at high steam pressures. It is a double-acting pump, although it has only one gland to require packing. It occupies a minimum of space; has no levers or tappets to get out of order; provides perfect cushioning of the steam piston; has an automatic draining device and runs with a full stroke even at the slowest speed. It is undoubtedly the finest pump on the market. If interested, write us, or better still, visit our plant and see the Hepburn Pump made.

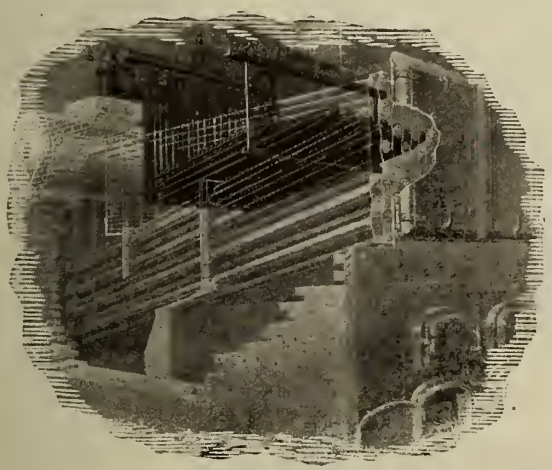
MORE VALUE FROM FUEL

BY INSTALLING

ELESCO SUPERHEATERS

Heat losses, because unseen, often escape notice.

Their existence, however, is responsible for the waste of upwards of 20% of the fuel consumed for the generation of power through the medium of steam.



Much of this fuel is wasted because the utmost utility of the steam is not obtained. Steam attains its highest commercial value when it is used SUPERHEATED, because at such temperatures it produces power most economically. The application and use of superheated steam is the practical way to get more real value out of fuel, because fuel is consumed for a given power output. You can reduce the operating cost of your plant by installing Elesco Superheaters. Our Bulletin T-5 explains why. Send for it.

You Can *Save* One Shovelful from Every Six Now Burned

More than one shovelful from every six is being wasted in plants without CO_2 Equipment. Granting that the firemen are doing their best, their "Best" usually falls considerably short of accurately gauging furnace combustion and preventing this waste. But a big part of this wasted coal—approximately one shovelful—can be turned into power units by the installation of a Republic CO_2 Recorder.

The operation of a Republic CO_2 Recorder is marvellously simple. Placed anywhere convenient on your furnace it represents by a continuous line the CO_2 percentages for every hour and every minute of the day. How simple a matter for your firemen to make the necessary adjustments and maintain continual maximum efficiency. And aside from the actual coal saving, Republic Charts place at your finger tips important operating facts hitherto unknown.

Republic CO_2 RECORDERS

base their efficient and economical performance on the following construction-features — features not found in ordinary meters:

1. Extreme simplicity. No valves, no small tubing and no glass parts to collect gases or sediment and develop trouble.
2. The hand is adjusted so that the operator can easily see the last record.
3. The records actually keep pace with the furnace.
4. The entire instrument is complete in an easily adjustable case, weighing only 45 lbs.

There are additional features—fully explained in our catalogue. Write for your copy to-day.

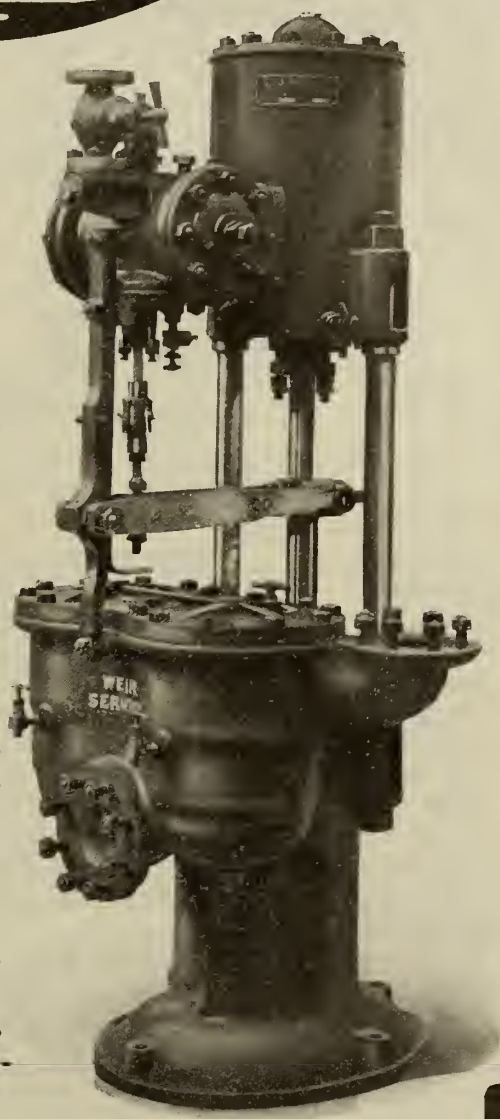
WEIR AUXILIARIES

Single Acting Simplex Feed Pumps
Turbine Rotary Feed Pumps
Compound Feed Pumps
General Service Pumps
Direct Contact Heaters
Multiflow Heaters
Evaporators and Distillers



Single Payment Insurance

When insurance companies sell you an accident insurance policy they guarantee to make certain payments to you—but you have to be hurt to get them.

When you purchase Weir Power Plant Auxiliaries you have, by paying their initial cost, taken out a single payment insurance policy from which you benefit from the day of their installation.

If you are considering the installation of power plant auxiliaries, write for full particulars of the various Weir Products in which you are interested.

D.C. without Conversion Losses

IF direct current is wanted, produce it directly from steam by means of De Laval turbine-driven direct-current generators. In small sizes the generator is run at the turbine speed, but in medium and larger sizes, the De Laval Speed-reducing Gear is used in order that both generator and turbine may show high efficiencies and to eliminate vibration and commutator troubles.

DE LAVAL turbine-driven D.C. generators are more efficient than engine-driven units, and they also show large savings over the generation of A.C. current and its subsequent conversion by means of transformers and rotary converters.

AS compared with reciprocating units, many packings, lubricated bearings and valves and other parts are avoided, and as compared with A.C.-D.C. conversion, cables, transformers, switches and the rotary converter are eliminated. The De Laval turbine-driven D.C. set will produce current at least cost and give you no trouble.

DE LAVAL Turbines are built for all-steam conditions and our engineers will give you the benefit of their experience with high-pressure condensing, non-condensing, low-pressure and mixed-low installations.

VALVE LEAKAGE

When slip due to valve leakage in the water end is added to thermal losses in the steam end the final efficiency of the average pump becomes very low.

To be successful, pump valves must be selected to suit the diversified requirements of pumping service.

Garlock Pump Valves are scientifically compounded and prepared for each special service.

Morrison Steam Goods

The Maintenance of a Reputation

Steam Specialties stand or fall upon their reputation for absolute and unvarying quality. That "like begets like"—that the same quality be apparent in every specialty—this is a vital necessity in the maintenance of a reputation. For over forty years recognition of these facts, and an earnest striving to live up to them, have characterized all Morrison products.

"Every installation is a demonstration of merit."

"OUTSIDE BONNET CONSTRUCTION"
Strong where others are weak

THE OUTSIDE BONNET CONSTRUCTION

(FOUND IN ALL PENBERTHY VALVES)

is the first progressive improvement made in valve construction in years past. It has many advantages over the old-style "Screwed-in Type" of bonnet for these reasons—

The threads are on the outside away from the corrosive action of the steam and water, consequently the valve can be taken apart easily and with no strain or injury to any parts.

There is no danger of spreading or enlarging bonnet end of body when tightening down bonnet to place, because the bonnet fastens to body by outside threads. This eliminates the danger of a loose-fitting and unsafe bonnet, which is possible in the old-style construction where the bonnet screws into the body.

Can you really afford to be without this high-grade valve?

TRADE PENBERTHY MARK.

PENBERTHY VALVES are too high grade to be imitated, *BUT* you may be offered a substitute. For your protection look for our name, which will be found on EVERY GENUINE PENBERTHY VALVE.

Detroit Stokers

In Refrigeration Plants

Detroit "V" Type Stokers are a highly profitable investment for the modern refrigerating plant. They reduce fuel cost 10% to 25% and labor cost 25% to 75% over hand firing. Automatic in all operations, they mechanically feed and distribute the fuel and remove the ash and clinkers.

Detroit Stokers are rugged in design and built for long wear with low repair cost. High boiler ratings can be maintained economically with practically any grade of fuel.

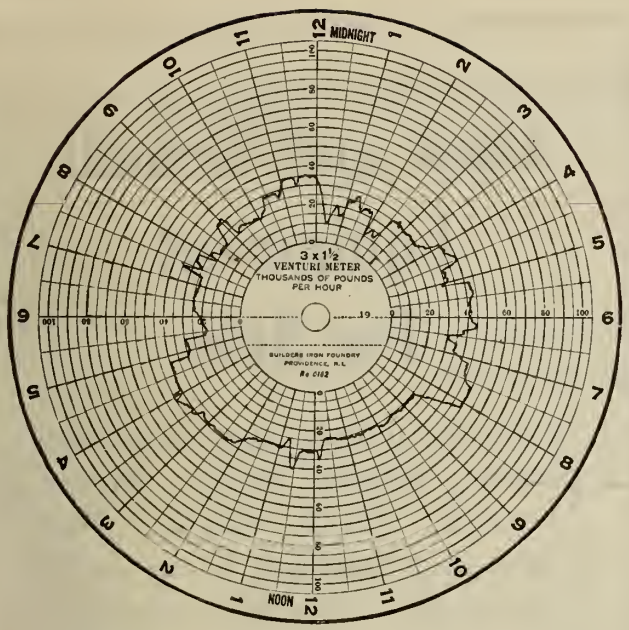
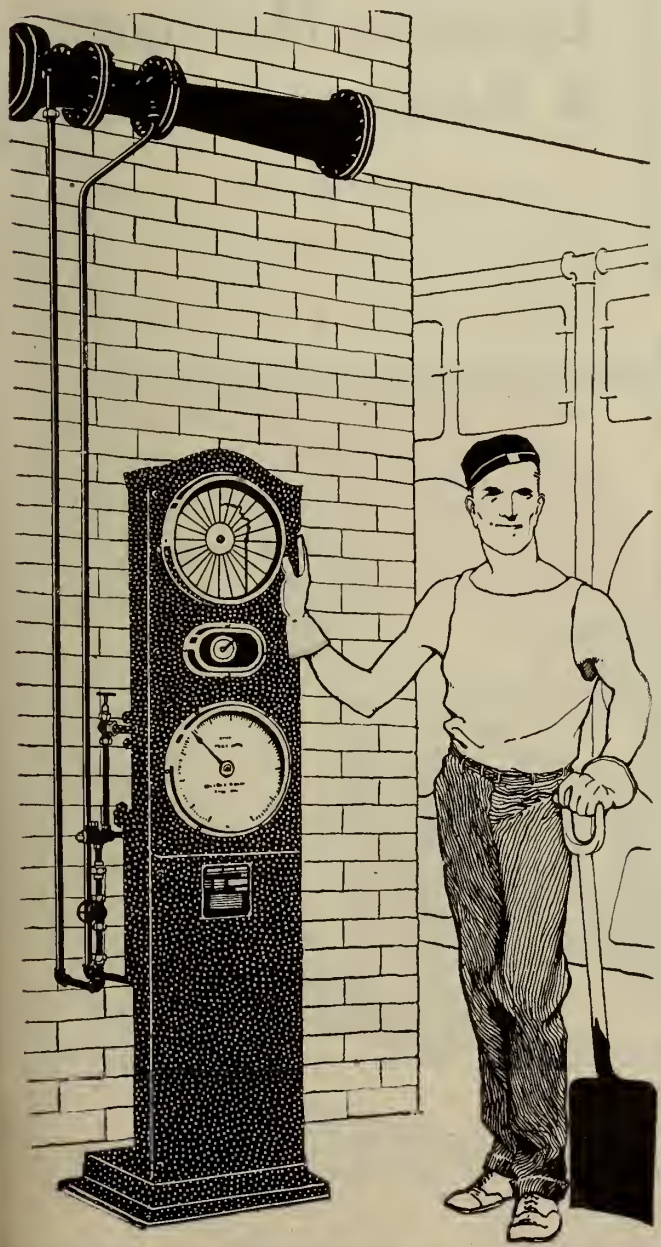
Gentlemen:
Referring to your communication of the 14th, we are pleased to advise that the seven stokers that you installed in our Central Plant in the year 1912 are working to our entire satisfaction, and if we should at any time decide to install stoker equipment at any of our plants, we will very favorably consider Detroit equipment.
Yours truly,



This chart shows economical boiler feeding



FIRM FRIENDS

The Efficient Fireman and the Venturi Meter!

It is only the lazy and careless boiler tender who has no welcome for the Venturi, since it clearly reveals daily his wasteful methods.

The man who is alive to his employers' interest and who realizes that every possible B.t.u. must be squeezed out of the costly coal pile points with pride to the improvement he has made "since the Venturi was installed."

Bulletin No. 197, "Why Your Power Plant Needs a Venturi," is Ready.

Less Wear and Tear

IMPERIAL Lubricants keep plant machinery running smoothly, reducing friction and consequent power loss.

Their regular use prolongs the life of your equipment, and increases its efficiency.

Imperial Lubricants are graded to meet the varied requirements of every type and make of machine. Each grade of oil is refined to the same exact, scientific standard. Ample supplies—every grade—carried in stock near you.

Many Imperial Oil customers voluntarily report savings as high as 35% in lubricating oil bills when following our recommendations. That's worth while economy that goes along with increased capacity and lowered depreciation costs.

Imperial Lubrication Engineers will gladly make it their business to see that you get full value from the lubricating oils you use. It will pay you to call in the Imperial Oil man and have him prescribe for your plant.

Write to 56 Church Street, Toronto, for more information.

Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO., Ltd. Hamilton, Canada - Quebec Branch: 51 Duluth Bldg., Montreal

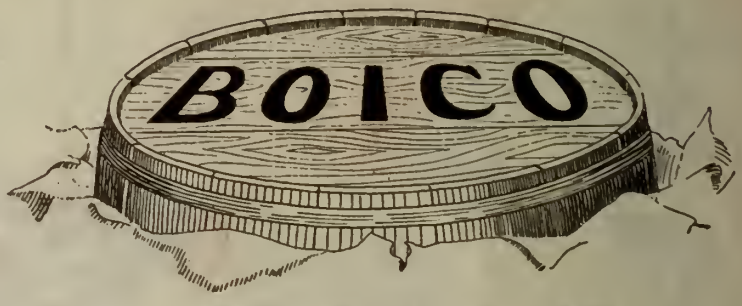
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

VULCABESTON

A Size for Every Leak

YARWAY Pipe Clamps are made in all the usual pipe sizes from ½″ to 24″. They will stop most any leak, large or small, ammonia, steam, water or air—stop it completely and permanently. Can be applied by any workman in a very few minutes. The Yarway Pipe-Joint Clamp stops leaks at joints; the Yarway Holtite Pipe Clamp stops holes and splits in straight pipe. Cost is but a fraction of the expense of a neglected leak or what you would pay for taking down the line. Keep a supply on hand for emergencies.

Jenkins Valves

Made *for* Maximum Service

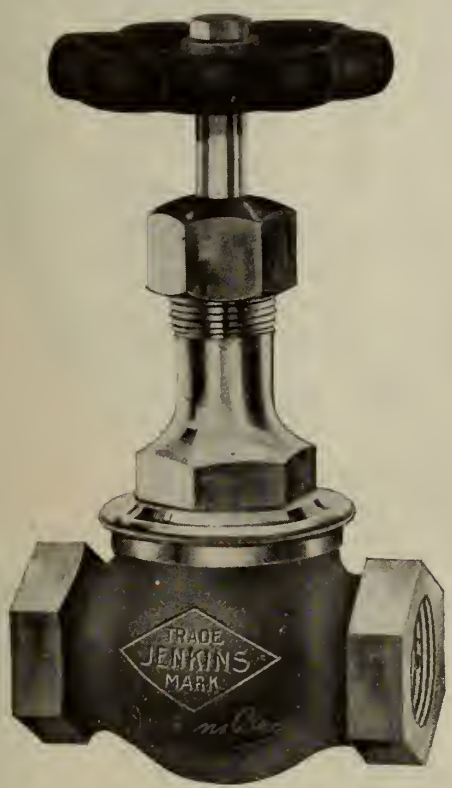

Fig. 106
JENKINS BRASS GLOBE VALVE
Suitable for 175 lbs. Working Steam Pressure or 250 lbs. Working Water Pressure.

The dependability and longevity of genuine Jenkins Valves are due to the fact that every valve in every type is made for the Maximum Service.

The man who knows valves and valve requirements installs Jenkins. Their trouble-free record in every branch of Service is a guarantee of satisfaction even under unusually severe conditions.

Jenkins Valves for every service are obtainable at supply houses everywhere. The line is very complete, including valves of brass, iron and cast steel for all requirements of power plants, industrial establishments, plumbing and heating service, etc. When buying look for the name "Jenkins" within a Diamond Mark on the body of the valve. It's there for your protection.

Catalog No. 8 describes the entire Jenkins line. Send for free copy.

Stoker

Five Months o Steady Overload

Boilers in plant were l on line conti ously for months at 1 to 250% of ing. Name request.

Three Months Continuously—Peak Loads at 340%

Such is the operating record of this "A-C" equipped plant. Name furnished on request.

Three Months of Continuous High Capacity

Boilers were kept on line continuously for over three months. Loads varied from 75% of boiler rating to 250%. Name furnished if requested.

Service that Costs Less Per Year

Most plant owners and operators know that mechanical stokers are today a necessity from the standpoint of economy. Of course the stoker that gives lowest cost service is the stoker these power users want.

An investigation of the operating records of Jones equipped plants will convince them that Jones Stokers *do* give lowest cost service:

—that when the immense saving of these stokers is considered, first cost *is* lower.

—that because of their rugged simplicity—unequalled by any other multiple retort stoker—maintenance costs *are* lower.

—that their ability to meet high peak loads and heavy overloads, and maintain overloads constantly—confirmed by the plant records opposite—*does* mean still greater saving.

—that the saving of labor because of the ease of manipulation *is* greater.

—that the under-feed principle, as enhanced by improvements and refinements in Jones design, *does* mean greater economy in burning Canadian coals.

Jones Stokers are made in two types: Jones "A-C" (Automatic-cleaning) Stoker for highest-duty requirements, and Jones "Standard" Stokers for a wide range of service.

Jones engineers will investigate your plant conditions and advise the type best suited to your own plant conditions.

The Canadian Stoker
JONES STOKERS are made in Canada by Canadians and sold for Canadian money at par. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been reorganized, and the reorganization makes available for Canadian power users, the extensive engineering resources of the Under-Feed Stoker Co. of America.

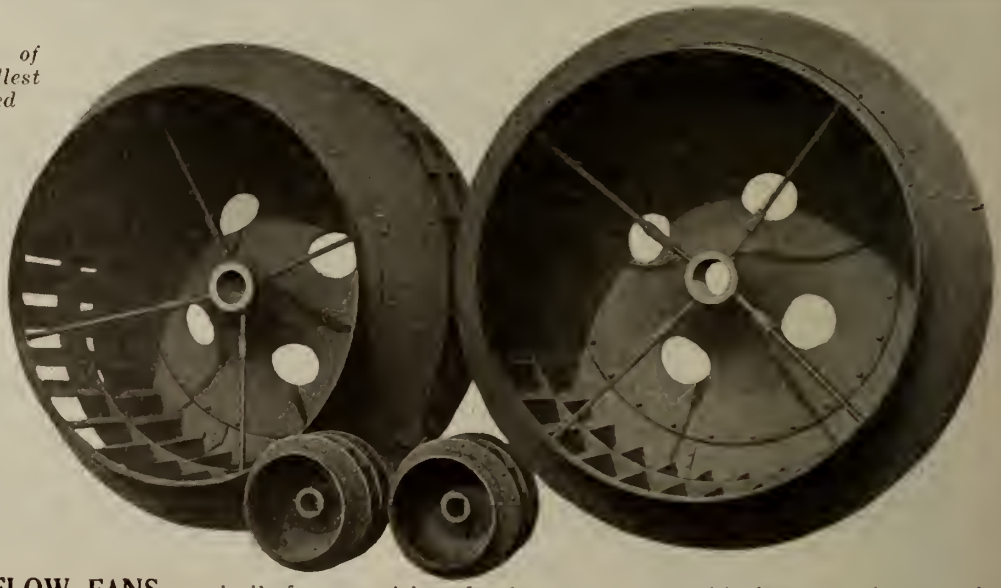
Comparison in Size of the Largest and Smallest Fans Manufactured

More Draft for Less Power



GREEN'S RADIAL FLOW FANS are built for capacities of 1,600 to 275,000 cubic feet per minute and pressures up to 7 in. of water.

These fans, besides having low horsepower requirements, operate at the most economical speeds for direct connection to turbines and motors, making possible small high speed efficient units.

Fans are built in two types—"RB" and "RR"—for forced and induced draft, respectively.

Our Engineers will be glad to submit data covering the requirements of your individual draft problem. Let us send full details.

GREEN'S ECONOMISER, LIMITED.

Take a "Look-See"

as the Chinaman would say, into the heart of the boiler room, the furnace. If you find loose and broken bricks and crumbling mortar in the lining, there is the cause of heat loss and incomplete combustion.

PLIBRICO JOINTLESS

FURNACE LINING

will make any furnace absolutely air-tight and gas-tight. No joints where clinkers may stick, no mortar to fall out, no chance for heat loss that eats into your coal pile.

PLIBRICO is a high-grade refractory which comes in plastic form, easily installed. No skilled labor is needed. Ideal for baffle walls, side walls, front-door arches, and combustion-chamber arches.

Comes in steel containers of distinctive appearance as shown at the right. Warehouse stocks ready for delivery at Montreal, Toronto, Winnipeg, Vancouver and Calgary.

Send for interesting booklet L14 on Furnace Building.

No Stoker is Better Than its GRATES

MURPHY AUTOMATIC FURNACES

Back of every feature of MURPHY GRATE construction are *many* sound reasons. Consider how these features save you dollars—in fuel—in labor—in maintenance.

The long—narrow—but deep sections give eighteen to twenty-eight square inches of cooling surface to every inch of exposed grate surface.

The liberal air space (47% to 52%) gives double the capacity of the boiler "without one penny for draft."

The correct proportion and distribution of ribs on the stationary grates, combined with the greatest accuracy of machine moulding have solved the sifting problem. The continuous movement of the ribless grates ¾" above and ¾" below the surface of the stationary grates—breaks up the fuel bed—prevents avalanching—keeps the grates clinker-free—and advances the ash gradually to a point where it is removed by the clinker grinder. It is this action that gives the Murphy Furnace the faculty of ***burning anything that has heat in it.***

Yet with all these advantages, the Murphy Grate of to-day is built to the same policy that has characterized every improvement. First, to make all parts standard; second, to make every piece interchangeable; third, to advise users of new developments so that they may keep their equipment up-to-date—and operating at top-notch efficiency.

For information on the Riley Underfeed Stokers for large boilers, see February 5 advertisement or send for Riley Stoker catalog HR-4

DURABLA

STRENGTH—GOODNESS—QUALITY

DURABLA Gaskets will give perfect service on ammonia joints in both absorption and compression systems regardless of the type of fitting.

The great value of DURABLA Gaskets in ice and refrigeration plant equipment lies in the fact that it can be used as a standard gasket on all joints giving equal satisfaction on any flange where a gasket is required.

Place DURABLA in the next joints you make and be insured against a costly shutdown due to gasket trouble.

Any amount of DURABLA Gasket Material, which is guaranteed to give perfect service in ammonia, air, oil, water, steam, gasoline and acid lines, will be sent on your written request to be paid for when found satisfactory.

Oil Filtration Means Economy

Bowser Systems for filtering and serving lubricating oil to bearings are constructed to meet all practicable conditions in connection with engines and other machinery.

A Bowser System provides a stream of cool, clean oil continuously. It reduces the consumption of oils to a minimum by using over and over again. In fact, a change from hand feed lubricating methods to a Bowser System will result in a saving of from 50% to 90% in lubricating expense.

D.S.P.—H.C. OIL ENGINE

For Central Service Station

THIS Made-in-Canada D.S.P.—H.C. Oil Engine is a four-cycle, single acting, heavy duty power unit, entirely self-contained and operates at high efficiency and constant speed under full or variable loads.

The unit consists of the engine, a two-stage air compressor, and container installed in the engine base for the storage of compressed air for fuel injection and engine starting.

D.S.P. Oil Engines are started cold within a few seconds and attain their rated capacity almost immediately. The operating cost stops when the engine is shut down, so there are no stand-by losses such as occur when fires are banked and attendance has to be maintained.

This is one of the most simple, durable and economical engines ever built and these claims are backed up by performance under actual working conditions of the most severe kind.

D.S.P. Oil Engines assure continuous and satisfactory service.

There are many interesting features which are fully illustrated in Bulletin No. 21. Write for it giving a general outline of your requirements.

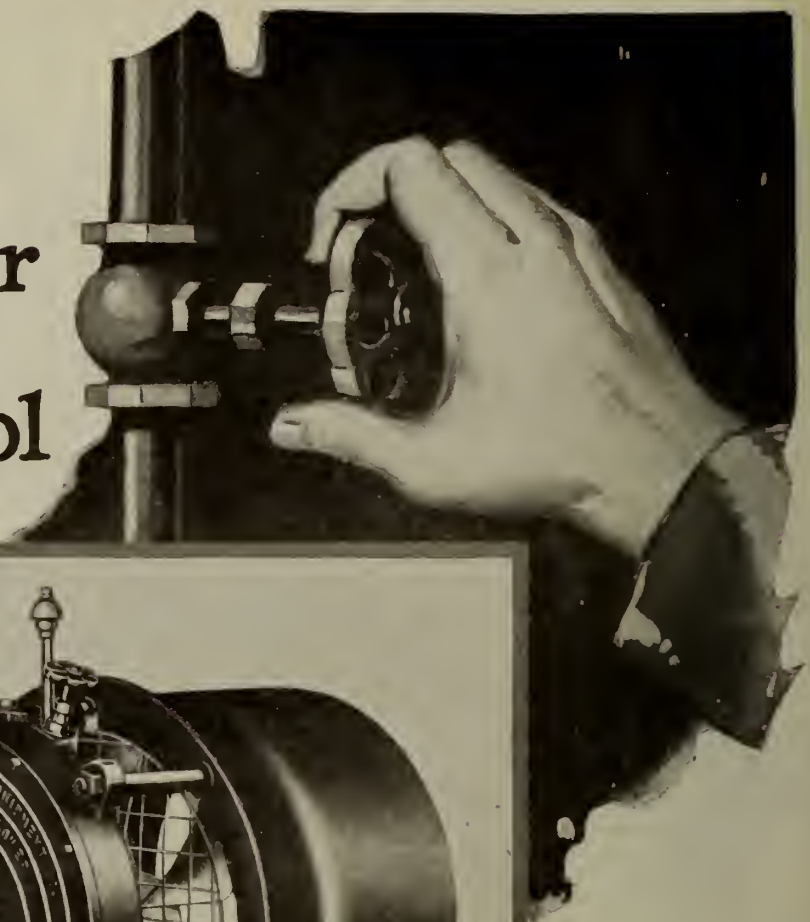
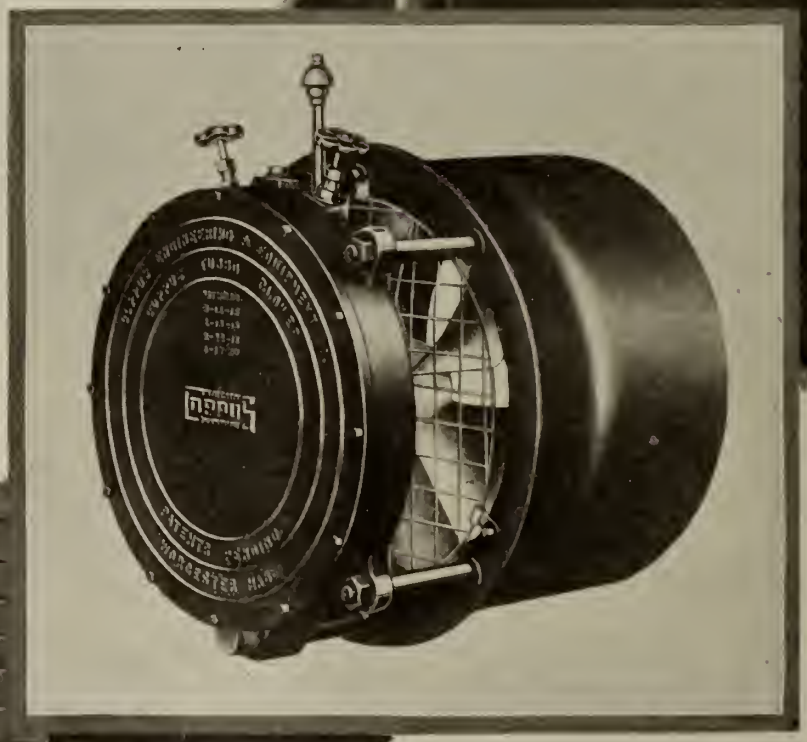
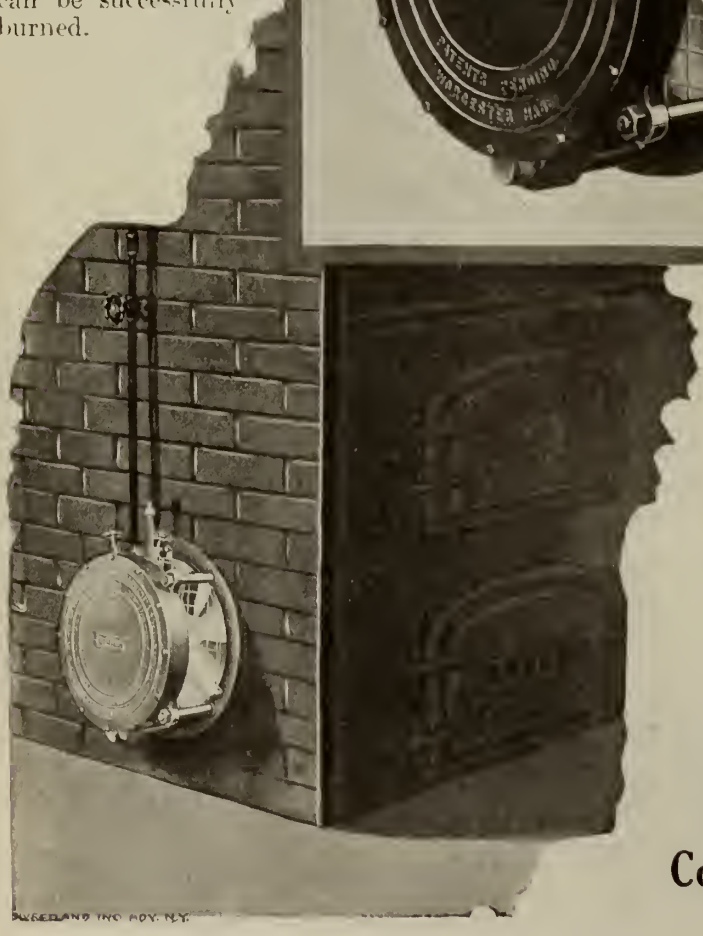
Turbo Blower
will give you
Valve-Control
of your fire



ONCE unheard of — to-day standard practice in our most efficient boiler plants — *valve control of your fires.*

A turn of the valve gives an immediate "pick-up" of your fires. More steam in a hurry — and, mind you, the cheapest and poorest grades of coal can be successfully burned.





It is almost as easy to install a Coppus Turbo Blower under your boilers as it is to put an electric fan in your office. Merely cut a whole in the boiler setting — mason in the casing — make the simple steam connection, and it's done. Then you have valve-control of your fire — as easy as regulating the flame of a gas jet.

Coppus Turbo Blowers are standard equipment in efficiently operated boiler plants.

Our booklet contains interesting blower data. Ask for it.

TAYLOR STOKERS

THE Taylor Stoker is a combustion system which burns all grades of bituminous coal satisfactorily—even low grade bituminous coal is burned with good results. It will operate boilers at immense overratings and will carry violently fluctuating loads with high efficiency. The Taylor Stoker does this because the coal is fed and burned on scientific principles, mechanically applied. It solves the coal problem as well as the labor problem in the power plant, and in its ability to carry heavy overloads continuously and easily it stands alone.

The Taylor is more than a stoker—it's a complete system of combustion. What it does, what it is and how it operates, is fully explained in "To-day's Problems and the Taylor Stoker." We will gladly mail you a copy on request.

Producing Ice in an Up-To-Date Plant

The New Plant of the Lake Simcoe Ice Co. at George Street and Esplanade, Toronto—Output of Eighty Tons Per Day—Some Interesting Apparatus is in Use

By T. H. FENNER

WHEN the driver brings the 25 or 50 pound block of clear ice to the housewife's refrigerator, it is safe to say that she loses no time in thinking of the process that has delivered it to her. That process has been a very elaborate one, involving the use of expensive machinery and much thought on the part of designing and operating engineers. Refrigeration has become a very important part of our modern civilization, and that branch of it which is devoted to the making of ice very necessary to our comfort and health in the summer months. We had these thoughts in mind when we recently had the opportunity of inspecting the new ice-making plant of the Lake Simcoe Ice Co., Limited, at the foot of George Street.

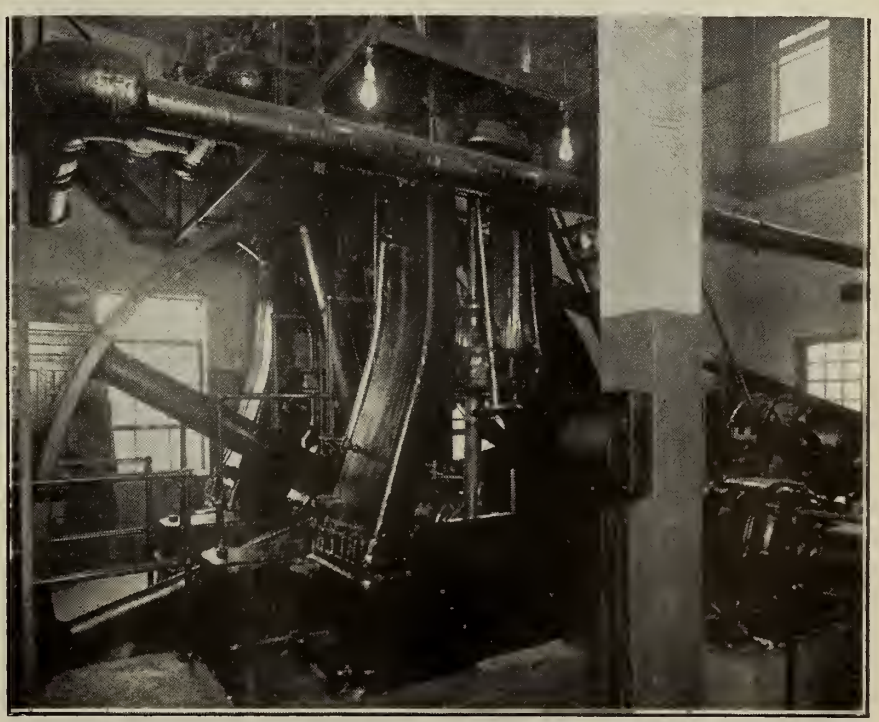
The George Street Plant

The plant which we are about to describe was erected last year, and started working in August. The machine was installed by the Canada Ice Machine Co., and is a twin compressor, made by the York Manufacturing Co., with fly wheel in the centre, motor driven, and rated at 57 tons ice making capacity. Most of our readers are aware that there is a distinction between ice making and refrigerating capacity, the refrigerating ton being based on the freezing of one ton of water into one ton of ice from and at 32 degrees F., in the twenty-four hours. The latent heat of ice being 144, this makes 288,000 B.t.u. per 24 hours. Ice making capacity is generally less than refrigerating capacity, in proportion to the difference in temperature between the water used and that of water at freezing temperature. Actually it runs from one-half to two-thirds the refrigerating capacity. This plant performs consistently better than its rating, the average daily output being between 79 and 80 tons of ice. The building contains the engine room, or we should say, compressor room, the ice making floor, a shipping room, and a 5,000 ton ice storage. The ice storage house is refrigerated with direct expansion coils, the same system being used in the shipping room storage. The ice making tank is refrigerated with both brine and direct expansion coils, the coils being placed between the container spaces in a stand ten pipes high.

The Compressor Room

The compressor room contains the main compressor, the auxiliary compressor, an air compressor, the brine tank, air storage tank, and the motors for driving the air and ammonia compressors. The liquid receiver from the ammonia condensor is also situated in the compressor room, and the expansion valves to the various refrigerating coils are also situated here, so that the man in charge has everything under control with a minimum of movement. The gauge board is set on the wall at the right hand side of the compressor room in such a position that it can be read from almost any point in the room. The motor driving the main compressor is a 200 H.P., 3 phase, 480 R.P.M. induction motor, made by the Canadian Westinghouse, and drives through a belt to the flywheel of the compressor. The bearing lubrication on the compressor is looked after by a small geared pump, which elevates the oil from the crank pits to a tank fixed on the top platform, and after filtering it runs to the various bearings by gravity. Telescopic oil pipes are used on the crosshead and crankpins. The compressor glands are fitted with universal tightening gear, operated through a rack and pinions on each gland, the pinion shaft being brought down the side of the column to a hand wheel in easy reach of the operator.

During the winter the main machine takes care of the ice making and cold storage, but in the summer months the small machine is put on the storage space and the main machine is kept strictly for ice making. The ice making goes on night and day all the year round, except-



THE 57-TON ICE-MAKING CAPACITY COMPRESSOR.

ing for a short stop for overhauling during the winter.

The pressures carried are the usual ones, the suction side carrying about 10 to 15 pounds per square inch, while the condensor side runs at from 165 to 180 pounds per square inch. The higher pressures will depend on the temperature of the condensing water, and the actual condition of the condensor itself.

The ammonia from the discharge of high pressure side of the ammonia compressor goes through a double pipe condensor situated on the same floor as the ice making room, which can be seen plainly in the illustration. The condensate passes to the liquid receiver in the engine room, which is situated directly below the condensor, and thence to the brine tank, the ice making tanks, and the direct expansion coils in the storage and shipping rooms. The ammonia after being boiled and extracting heat from the brine and storage rooms, is brought back to a common suction receiver and then drawn into the compressor to resume its cycle.

This part of the plant is the usual type of refrigerating apparatus. It is when we come to the actual ice making part of the plant, which the refrigerating machine serves, that the interesting features are found.

VIEW OF DOUBLE PIPE CONDENSOR.

The Ice Making Room

The ice making room is shown in our illustration, and this is, of course, the main part of the plant. The illustration gives a clear idea of the layout, and we can consider the process in detail with the assistance of the detailed illustrations shown.

The water comes into the plant through filters filled with charcoal and sand, which effectually remove any impurities which may have got into it in its passage through the city mains. After passing through these filters it goes into a larger tank, which serves a double purpose. It is of large enough capacity to act as a settling basin, and besides that a coil is taken from the ammonia pipe on its way back to the suction side of the compressor, and passes through the tank, thus acting as a forecooler to reduce the water temperature before it goes into the cans. The ice making tank has a capacity of 572 cans, each of which contains 400 lbs. of ice after being frozen. The containers, or cans, which are to be plainly seen in the illustrations, are handled in pairs, and the amount of time allowed for freezing is about thirty-five and a half hours. The freezing is accomplished by lowering the containers into a bath of brine, through which the direct expansion coils are laid, and which is kept continually agitated by two motor-driven agitators at one end of the tank, besides the circulation due to the pump. The city water after filtering and forecooling is piped off to two rubber hose pipes, at the end of each being the automatic filling arrangement. This can be seen in the illustration, and consists of a brass stand for holding the pipe, and a delivery nozzle, to which is attached a trigger operated valve and a ball float. The filling of the containers is accomplished by putting the delivery pipe into the container, where it is held by the brass stand. It is allowed to go into the container just so far, that when the water is at the desired height the water will operate a float attached to the delivery pipe. This float lifts with the action of the water, and kicks off the trigger of the valve, which immediately closes. The containers, when first dropped into the brine, are, of course, buoyant, but they sink as the water gradually fills them, until when they are filled they are down in the brine to their full length. The brine in the freezing tank is kept at a temperature of about 10 degrees above zero, and the freezing process starts immediately the containers are put in.

THE ICE MAKING FLOOR.

In order that the ice shall be clear, and free from cloudiness, it is necessary to keep the water in the containers agitated during the whole time that they are being frozen. In order to do this, a jet of compressed air is delivered to each can at a pressure of about 18 to 20 lbs. per square inch. As the water freezes, it expels all impurities, and as it freezes from the edges of the can towards the

THE HOIST IS READY TO LIFT TWO FROZEN CANS, TWO EMPTIES HAVE JUST BEEN DEPOSITED, AND ON THE RIGHT TWO CANS ARE JUST FILLED.

centre, these impurities are forced into a very narrow space in the centre of the block of ice, and thence forced upwards towards the open end at the top of the container. Thus there is left a small cavity or pipe at the top of the block, much like the pipe in the top of an ingot of steel, and as in the ingot, containing all the impurities, which can be cut off. The path of escape of the imprisoned air and any impurities that may be present can be traced in the otherwise clear block of ice by a very narrow fin that starts near the bottom of the block and reaches right up to the bottom of the cavity just mentioned.

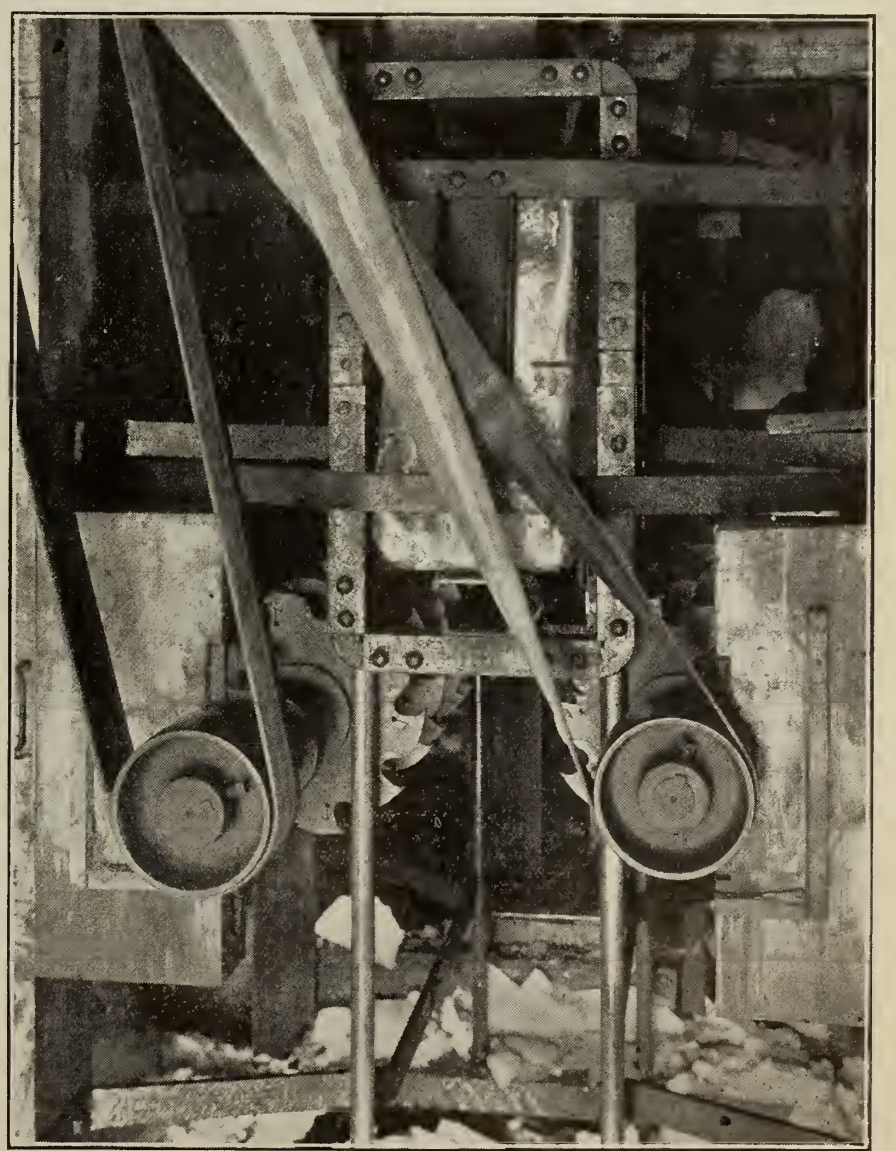
The air that is used for agitating the water in the containers is supplied by the air compressor, as previously stated. This air is also cooled before being delivered to the containers by being passed through the brine tank by means of a coil. The air compressor delivers to a large storage tank in the compressor room, and the discharge from this tank is piped up to the brine tank. The air storage tank is large enough to ensure a supply of air for an hour if by any chance the power should go off, or it should be necessary to close off the compressor for any reason.

The Operating Routine

Having seen how the freezing of the water is accomplished, and the methods employed to obtain clear ice, we may now look into the production part of the business, which is a very important feature from the commercial standpoint, as well as from the engineering view.

We have seen that the total capacity of the ice making room is 572 cans of 400 lbs. each. The actual number of cans pulled per day is 396, and the system employed is about as follows: The time allowed for freezing is just about one day and a half, so that a container filled at midnight one day would be pulled out at noon on the second day following. The men on the floor pull the frozen cans out in pairs, by means of the traveling electric hoist seen in the picture, and carry them over to one side of the room, where they are left to stand till their temperature has risen from that of the brine tank to about freezing point.

There are a number of full cans always standing on the floor, going through this process of tempering as it is called, and after the hoist man has deposited the two latest, he takes his hoist along to two other cans, which have been pulled earlier, and are now at about the temperature of freezing, or a little below it. He takes these two cans and lowers them into a sump, or hot water tank, the effect of which is to loosen the block of ice from the sides of the container. This process is little more than a dipping, and the containers are now lifted out again, and taken to the swinging carriage, which can be seen in the general illustration of the ice making room. This carriage is then swung over and the block of ice slides out, and is directed by means of a wooden guide



SAWS FOR NICKING ICE BLOCKS.

TURNING OUT THE BLOCK FOR CONTAINER.

or valve, to one side or other of a hoist, or gig, which operates automatically.

Meanwhile, the man on the floor has not been idle. Looking at the illustration one may notice that the hoist man has coupled on to two full cans, while he has just deposited two empty cans, and there are still two others which are being filled and are just about up to their level. In this way these two men handle about eighteen cans per hour. The time allowed for tempering is about two hours, which means that there must always be a supply of cans ahead of the men.

When the block of ice is shot out of the container it is guided to the hoist, which has two compartments. These two compartments lead, when the hoist arrives at the lower floor, to two passages, which the ice descends by gravity. One of these leads to the shipping room and the other to an arrangement of saws.

The hoist itself is absolutely automatic. It consists of three parts, the ice carriage, a counterweight, and an air cylinder with a double piston. The counterweight is heavy enough to overbalance the gig or hoist when it is empty, but not when there is a block of ice upon it. The hoist is attached by a cable to the piston rod of the air cylinder. This has a valve at the top and one at the bottom, and the piston is made with a double leather washer. The action is that when a block of ice is put on the hoist, it overbalances the counterweight, and the hoist goes down. In order that it shall not go too quickly, it has to pull the piston of the air cylinder up against the air in the cylinder, and the speed at which this can escape is regulated by the opening of the valve on the cylinder end. The same method applies in the reverse direction when the ice is taken off at the bottom of the hoist. The counterweight then pulls the hoist up, and in order that it does not go too quickly, it is checked by the opposite side of the piston.

When the ice arrives at the bottom of the hoist, it may go to the storage or to the saw. If it is to be supplied for car refrigerating or cold storage, such as butchers, it goes to the storage just as it is. If it is to be supplied to the drivers for the household trade it goes to the saws. These saws nick the block in a horizontal direction, through the centre, while at the same time nicking it on the side vertically. The result is to divide the block exactly into eight twenty-five pound blocks, which, while all contained in one, only require a prod from the driver's pick to break off into exactly weighed pieces of twenty-five, fifty, or seventy-five, or whatever the case may be. This does away with the use of scales, the necessity for chopping and wastage resulting, and also the possibility of dispute. Our photograph shows the saws with a block of ice in place.

The last photograph shows the ice being shipped on to the delivery wagon and it can be seen how clear it is.

The plant is modern in every way, and the results obtained are certainly satisfactory. From a production standpoint with a minimum of labor it commends itself highly to the observer. One pleasing feature of the plant was the absolute cleanliness observed throughout. It was also good to note that real good accommodation for washing, etc., had been provided for the men employed about the plant.

We wish to express our appreciation of the courtesy of Mr. Newnham Fairhead, the company's chief engineer, who personally explained the leading features of the plant on the occasion of our visit.

THE FINISHED PRODUCT.

TECHNICAL PAPER

The United States Bureau of Mines announces the issuance of Technical Paper 254, "The analysis of sulphur forms in coal," by Alfred R. Powell, organic chemist.

This paper describes and elaborates the method for the determination of the various forms of sulphur in coal as originally outlined by the author while working with Prof. S. W. Parr at the University of Illinois. The method, which at that time was found to be applicable to Illinois coals, is shown by the results of the present investigation to be accurate when applied to coals from widely different fields. Certain changes and optional methods of procedure are suggested which it is hoped will make the method conform better to routine and rapid commercial analysis.

Copies of Technical Paper 254 may be obtained by applying to the Director of the Bureau of Mines, Washington, D.C.

Mechanical Stokers in Refigerating Plants

Advantages of Mechanical Stokers—A Canadian Example—Standardized Firing Practice—Some Results of Stoker Tests—Some Details in the Handling of Stokers.

By ROBERT JUNE

POWER is one of the largest items of expense in most manufacturing businesses, and the cost of fuel represents on the average 70 per cent. of the cost of power. And the cost of fuel is going up. Nothing short of the discovery of a new source of power can stop the rising tendency of coal prices.

Since waste in the coal pile represents dollars which should be conserved for the dividend pile, it stands the power plant operator in hand to use the most economical grade of fuel.

The first point to bear in mind is that the most economical grade of fuel varies with different furnaces and methods of combustion. As an illustration: Coal selling at a very low price per ton may be more expensive to burn than a better grade of coal under certain furnace conditions. When these conditions are changed it may be found that a cheaper grade of coal is the most economical and that an appreciable saving in operating costs has been effected through the improvement in methods of firing.

The furnace is often the weakest link in the chain of economical steam production. The amount of coal burned to produce the results demanded is often far in excess of what would be required by careful, intelligent management. In many cases existing plants have been redesigned for a cheaper grade of fuel, and it is to-day becoming quite a frequent practice to design boiler furnaces, especially to permit the use of a low grade of fuel.

One of the conditions necessary to the efficient, and in particular the smokeless combustion of coal, is uniform liberation of the volatile gases. This is a condition which practically never can be realized in the hand-fired furnace. Inasmuch as the hand-fired furnace also presents pretty definite limitations in the way of utilizing the cheapest grades of fuel, we find that the way to improve boiler-room operating conditions is to install mechanical stokers.

Advantages of Mechanical Stokers

Among the advantages attaching to the use of mechanical stokers are the following:

A.—Hand firing is intermittent and its evenness and effectiveness depend on the individual skill of the fireman and the degree of attention which he accords his work. With the automatic stoker firing is continuous and uniformly even.

B.—Cleaning of fires in hand-fired furnaces is also intermittent and often erratic and is dependent solely upon the skill of the fireman. With stokers the fires are automatically and continuously cleaned, thus insuring increased efficiency in combustion.

C.—With hand-firing there is a constant opening of doors, thus admitting large quantities of cold air into the furnace. The depth of the fuel bed is also a variable factor and the amount of air that comes up through the fuel bed accordingly varies from one time to another. With stokers, on the other hand, it is possible to secure practically constant and uniform supply of air which can be controlled to agree with operating conditions.

D.—With hand-firing, one fireman can at the best take care of from 250 to 500 h.p. of boilers, whereas with automatic stokers one fireman can take care of 2,000 to 3,000 h.p. of boilers, hence the stokers reduce this item of labor cost 75 per cent. or more.

E.—One of the outstanding advantages of automatic stokers is their ability to burn efficiently cheaper grades of fuel than can be burned to advantage with hand-firing. The importance of this factor can readily be estimated as a saving in this direction alone may amount to enough to pay for the stoker installation several times over in the course of a year.

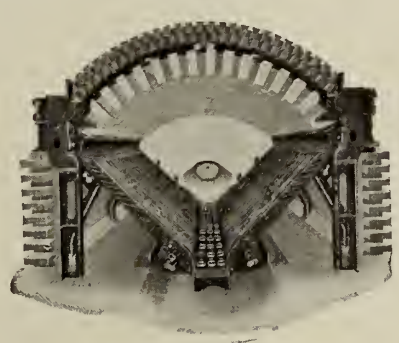


FIG. 1.—REAR VIEW OF STOKER. RADIAL ARCH.

F.—With hand-firing it is next to impossible to prevent the discharge of large amounts of smoke from the stack. This is due to the intermittent character of the firing and the lack of uniformity in the liberation of the volatile gases. With the stoker the smoke nuisance is to an appreciable extent within control.

The Case of a Canadian Refrigerating Plant

The writer's attention has recently been called to two Canadian refrigerating plants of approximately equal capacity. One of these plants had hand-fired furnaces, and further, the bad conditions of this type of firing had a psychological effect on those working in the boiler room. The place was in a generally ill-kept and unsatisfactory condition. The other plant was equipped with mechanical stokers of the side-feed V-type, and perhaps because the attainment of efficiency in combustion stimulated the firemen to better work all around, the boiler room was in first-class condition. The first plant was using half again as much coal as the second, and because of the very bad features of boiler-room operation the cost of steam generation was actually twice the cost of generation in the second plant.

A study of the psychology of the fireman who labors under adverse conditions is replete with interest. Too often he works in a dimly lighted boiler-room and with equipment so inefficient that any incentive he may have toward improving conditions becomes buried. Where careless management prevails, coal soon comes to mean to him nothing but a black substance of unlimited supply. When the storage space gets empty, coal cars or motor trucks refill it. The boss who pays for it makes no demands regarding the saving of fuel. The management's one demand is that steam should be kept up, and therefore why should he, the fireman, who shovels coal hour after hour and day after day be concerned with anything but the pressure gauge?

This was the condition existing in the first boiler-room. When the management finally took up the problem of reducing the cost of steam generation they found the firemen ready and willing to cooperate. When it was proposed to install stokers the management found the men actually welcoming the idea, although they realized that some changes would have to be made in the number of men working in the boiler-room. For this

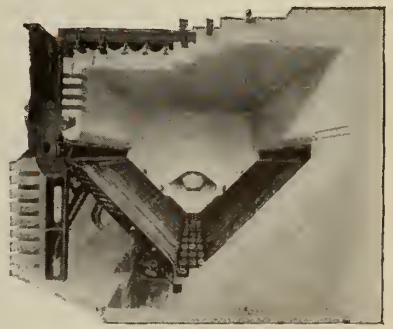

FIG. 2—REAR VIEW WITH FLAT SUSPENDED ARCH.

particular plant the type of mechanical stoker chosen was one which would operate economically with the natural draft, without an auxiliary fan or blower. After the installation had been completed it was found that a cheaper grade of fuel than had previously been used could be burned, and that due to the uniformity with which the stoker fed the fuel, the proper proportion of air in combustion, the absence of large amounts of excess air, the self-cleaning feature of the grates, etc., that it was possible to maintain a uniform boiler efficiency of approximately 70 per cent., whereas 55 per cent. had been the rule before, and that the same amount of steam could be generated with considerably less coal.

With the installation of the stokers a transformation took place in the boiler room. The firemen began to display a hearty interest in their work, with the result that the esprit de corps of the operators and the whole appearance of the boiler-room was changed. As a result, the cost of producing steam in this plant was reduced something like 50 per cent., bringing it down to the cost in the second plant. There has been no difficulty in maintaining costs at this low figure.

Standardized Firing Practice

Daily records are essential with any method of firing if economy is an object. These reduce to the low-limit the human element. From them is derived the proper adjustment of air supply, rate of feed, and depth of fire. It should be the aim of the operating engineer to standardize his firing practice.

When a condition of smokelessness of stacks is desirable by reason of local smoke-regulating ordinances, or because of its injury to the manufactured product (as in paper mills), the fact is that the best results can be obtained by the use of mechanical stokers. And the reason for this is that, as compared with hand-firing, there is a much longer time for combustion. As the volatile gases are distilled they are acted upon by ignition arches prior to coming in contact with the cooler heating surfaces. Otherwise they would fail of ignition and pass out of the stack unconsumed. Where space permits stokers may be installed so as to extend beyond the boiler front. This gives an added length of travel during which the gases are acted upon by the radiant heat from the ignition or supplementary arches, and are properly consumed.

Stokers, as has been stated, often reduce labor costs 50 to 75 per cent., or more. The slow-running, self-cleaning types require much less attention than hand-fired furnaces.

For boilers operating up to 200 per cent. rating the side-feed, V-type stoker, such as the type illustrated herewith, makes a desirable and economical installation. It possesses a much larger coking area than the other types of stokers. As the combustion area is likewise very large, it is possible to secure complete and practically smokeless operation. It operates with natural draft.

FIG. 4.—AFTER STOKER INSTALLATION.

Two magaines located on each side of the stoker supply the coal. Coking plates are inclined at a steep slope toward the center of the furnace. As the coal leaves the magazines it rests for a short time upon the coking plates. During this period the volatile gases are driven off and mixed with air which has been pre-heated by admission through the arch over the fire.

Gravity plays an important part in the operation of this type, and little power is required to actuate clinker crusher and oscillate grates. The fuel travels slowly from the inclined grates toward the clinker grinder, receiving the requisite amount of air through the grates to complete the process of combustion. By the time the lower portion of the grate is reached the combustion is completed, and ash and clinker are removed automatically. Maintenance cost is low, due to the small number of parts coming in contact with the fire.

Stoker boxes push the coal into the grates. The speed of this operation is easily regulated. As combustion proceeds the grates oscillate and have a slicing effect on the fuel. This permits free admission of the air and assures complete combustion. In stokers of this type the clinker grinders can be adjusted to operate independently of the remainder of the mechanism. If the coal contains a large amount of ash and clinker the grinder may be adjusted to operate faster to remove them. At the same time the coal may be fed at a slow rate if desired.

Results of Stoker Tests

The savings in coal effected by the use of mechanical stokers are very large. This result is to be expected in view of the fact that stokers increase the overall boiler efficiency from the general average of 55 per cent. for hand-fired furnaces to a general average of 70 per cent. for stoker-fired. As indicative of the high boiler efficiencies readily obtained from the use of

FIG. 5.—BEFORE STOKER INSTALLATION.

mechanical stokers we include Table 1, which shows results of a test at normal rating on Detroit stokers at the well-known American refrigerating plant of the Merchant's Ice & Cold Storage Co., Louisville, Ky.

A number of Canadian refrigerating plants are equipped with this type of stoker and outside of the refrigerating industry they are to be found in many other lines.

TABLE 1.

MERCHANTS ICE & COLD STORAGE CO.,
Plant No. 3 7th and Grayson. Louisville, Ky.
Test on one Detroit "V" Type Stoker.
Under One H.R.T. Boiler—66" x 18' 0" (Vogt).

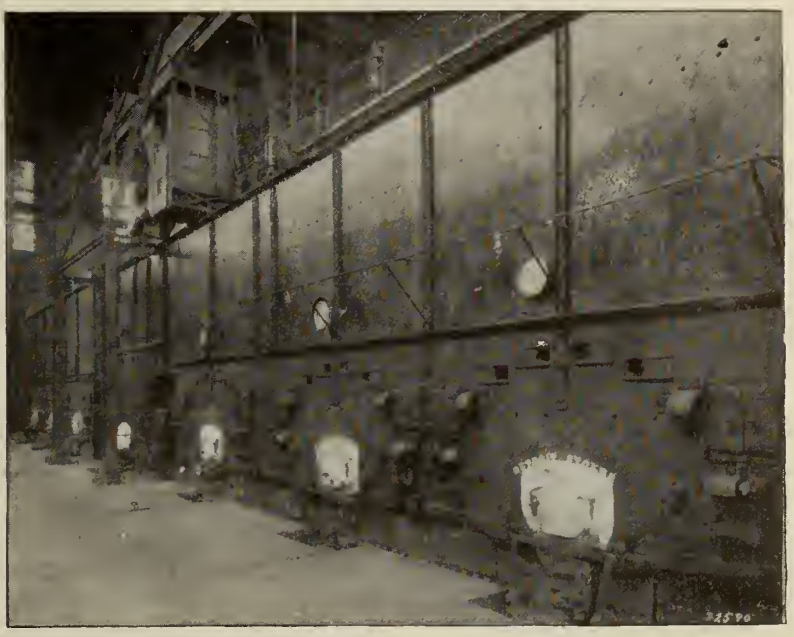
H.P. of boiler (owner's rating)	120 H.P.
Size of Stoker	4' 11" x 5' 3"
Grate surface	27 sq. ft. projected
Duration of trial	8 hours
Kind of fuel	Kenawa Gas Coal Slack
Total Quantities	
1. Duration of trial	8 hours
2. Weight of coal as fired	3,576 lbs.
3. Per cent. of moisture in coal	5.38%
4. Total weight of dry coal fired	3,384 lbs.
5. Total ash and refuse	463 lbs.
6. Per cent. of ash and refuse in dry coal	13.7%
7. Total weight of water feed to boiler	32,508 lbs.
8. Factor of evaporation	1.083
9. Equivalent water fed to boiler from and at 212°	35,206 lbs.
Hourly Quantities	
10. Dry coal fired per hour	423 lbs.
11. Dry coal per sq. ft. of grate per hour	15.66 lbs.
12. Water evaporated per hour	4063.5 lbs.
13. Equivalent water per hour from and at 212 deg.	4400.7 lbs.
Averages—Pres. and Temp.	
14. Steam pressure by gauge	99.6 lbs.
15. Temperature of feed water	170.3° F.
16. Temperature of flue gas	507° F.
17. Force of draft in breeching	.....
18. Force of draft over fire	.10"
Horse Power.	
19. Horse power developed	127.5
20. Builders' rated horse power	120
21. Per cent. of builders' rating developed	*106.3%
Economic Results	
22. Water evaporated per pound of coal as fired	9.09 lbs.
23. Equivalent evaporation from and at 212° per pound of coal as fired	9.84 lbs.
24. Equivalent evaporation from and at 212° per pound of dry coal.	10.40 lbs.
25. Equivalent evaporation from and at 212° per lb. of combustible.	12.05 lbs.
Coal Analysis	
Moisture	5.38%
Volatile carbon	.....
Fixed carbon	.....
Ash	10.0%
B.T.U. of coal as fired	13,088
B.Y.U. per pound of dry coal	13,833
Efficiency.	
Efficiency of boiler, including stoker, based on dry coal	72.6%

*Note.—Test purposely run at normal rating of boiler.

Details to be Remembered in Handling Stokers

Mechanical stokers are a good paying investment and they are badly needed in large numbers of plants where they are not now used. Do not think because you operate a small boiler that you cannot use a stoker advantageously. If your boiler plant is small you may not effect a large saving in labor by the use of a stoker, but you can gain greatly increased boiler efficiency, save fuel, and correspondingly lower your operating costs.

After your stoker has been installed the first thing to do is to determine standard practice for firing. A little experimental work done by one of your competent engineers will enable you to lay down the rules to be followed in handling your stokers. After the standard practice has been formulated it should be typewritten and placed at one or more points in the boiler-room and the work of the fireman should be checked regularly. Remember that rules are of value only if they are followed.



STOKER INSTALLATION IN A WELL-KNOWN POWER HOUSE.

Be sure that the following points are embodied in your rules for stoker operation:

A—Keep draft under close control at all times. It is very desirable to use draft gauges with all types of stokers.

B—See that your air vents are kept open, so that there will be no obstruction to the passage of the air.

C—Do not allow air leaks which may develop in the furnace to remain unattended to.

D—See that the ash pit is cleaned out regularly at frequent intervals. Check up the CO_2 in your flue gas regularly. If the percentage falls below standard find out why.

E—Remember that coking coal may require the use of a slice bar.

F—Do not under any circumstances get water upon the arches or brick work when you are washing out the boiler.

G—Do not stop the stoker engine when hopper is full of coal. If an emergency stop is necessary, clean out the hopper.

H—Attend to all maintenance work promptly and your repair bills will be small.

In conclusion, if you wish a high standard in boiler room practice equip your boilers with the necessary apparatus and assure yourself that your operatives are sufficiently familiar with the equipment in the plant to handle it intelligently under varying conditions of load.

Mr. E. L. Walker, assistant engineer in the plant of Messrs. Goldie and McCulloch Company, Galt, has the following to say about Power House: "I think that the course of instruction for the graded certificate now running in Power House is unsurpassed as a means of helping the engineer qualify for a higher certificate, and I am now making use of it in studying for my second class papers."

John P. Campbell, 114 State street, Galt, has just completed forty years' consecutive service as chief engineer for the Galt Knitting Co., Ltd. Mr. Campbell has been a subscriber to Power House for the past ten years, and when his eyesight gave out for reading purposes six years ago, Mrs. Campbell read it to him until her death three years ago. Since that time Mr. Campbell's son has done this for his old dad. When the writer called for Mr. Campbell's renewal, the latter said that he looked forward to the arrival of P. H. every two weeks with interest unsurpassed by any other event. Mr. Campbell has been in the engineering business in Galt for forty-five years. He will be seventy-one years of age next week, and right here we want to extend to Mr. Campbell our heartiest good wishes for many happy returns.

Mr. G J. Christie, chief engineer of Wisers Brewery, Prescott, Ont., has just completed twenty years of continuous service with that institution. Mr. Christie was born in Dublin, Ireland, in 1872, and came to Canada in 1886. He went in for lake boat engineering and sailed the lakes for fifteen years as an engineer. He entered the employ of Wisers in 1901. He is a keen reader of Power House, and says he will always manage to soak away $2 for his annual subscription.

Points on the Principles of Refrigeration

General Idea of the Refrigerating Cycle—A Few Common Definitions—Various Types of Refrigerants—The Different Systems of Refrigerating Cold Air — Compression — Absorption Machines

By "FRIG"

A GREAT many engineers who are familiar with steam and its elementary principles find a difficulty in understanding the refrigerating system, especially when they have had no opportunity to see it actually at work.

There should be little difficulty for a man who understands the broad principles of the steam engine to grasp those of the refrigerating machine. The processes in one are duplicated in the other, but in an opposite direction. Definite units are employed to define them, as in the steam engine, and there is a large amount of literature available from the most elementary to the most advanced methods of explanation. The purpose of this article is to define in a general way the principles and terms used for the benefit of those who have little or no acquaintance with this important side of engineering and create an interest that will induce them to pursue the subject further.

The Refrigerating Cycle

The performance of work by a steam engine is brought about by a working fluid, a source of heat which changes the working fluid from a liquid to a gas, the giving up of the heat stored in the working fluid by doing work on the piston of the steam engine, and the changing of the gas back to a liquid in a condenser, from which it is returned to the source of heat. In more familiar language the furnace is the source of heat, the water in the boiler is the working fluid, which is turned into steam by absorbing the heat from the furnace. A portion of this heat is given up by the expanding steam forcing the piston in front of it, and the greater part is carried away by the circulating water of the condenser. The condensed steam is pumped back into the boiler. If everything on boiler and engine were tight, the original charge of water would do indefinitely, but owing to leakages here and there a certain amount is lost and must be made up from time to time.

In the refrigerating system the source of heat, the working fluid, the piston and the condenser are all present, but their operation is reversed. The working fluid is a volatile liquid usually of low boiling point and high latent heat. The source of heat is the medium which is to be cooled, and may be the air of the room or a solution of brine. The working fluid which goes into the evaporator of the system, which corresponds to the boiler of the steam system, is changed from a liquid into a gas, absorbing heat from its surrounding bodies as the water absorbed heat from the furnace. It is then drawn into the compressor, which corresponds to the cylinder of the steam engine, but instead of doing work on the piston, it is compressed by the piston. In other words the piston of the compressor performs work on the gas, the result being that a further amount of heat appears in the gas. It is then discharged from the compressor into the condenser, where the heat is carried away by the circulating water, and the gas becomes a liquid again, ready to pass to the evaporator and perform the same cycle again. Now in both cases we have the application of heat to change a liquid into a gas, and the giving up of heat to the circulating water. However, we have the important difference that in the steam engine the fluid does work on the piston, while in the refrigerating machine the piston does work on the fluid.

In both these cases the first law of thermo dynamics is made use of, which is "Heat and work are mutually interchangeable, and produce every unit of heat required for its appearance, or produces by its disappearance 778 foot-pounds of work."

Some Definitions

The unit of work is the foot-pound, which is the work performed by lifting a weight of one pound one foot in height. The unit of heat is the British thermal unit, which is the amount of heat required to raise one pound of water one degree when at its maximum density, that is from 39 to 40 degrees F. The amount of heat that will raise one pound of water one degree or the B.t.u. is capable of performing an amount of work equivalent to raising one pound weight 778 feet high, or 778 pounds in weight one foot high.

As there is a unit for the work done by the steam engine, which is known as the horsepower, so there is a unit for the refrigerating machine, which is known as the refrigerating ton, or ton of refrigeration. The purpose of the refrigerating machine being to produce lower temperature or extract heat, its work is measured by a unit that easily expresses that capacity. A ton of refrigeration is the amount of heat that would be absorbed by one ton of water being changed into ice from and at the temperature of 32 F. in the space of twenty-four hours. The amount of heat would, of course, correspond to the latent heat of water, which is 144 B.t.u. per pound, or 288,000 per ton. Therefore the ton of refrigeration is the absorption of 288,000 B.t.u. per twenty-four hours. Latent heat is the amount of heat which must be absorbed by a body or given out by a body in order to change its state, at a constant temperature. That is in turning water into ice or ice into water, at a temperature of 32 degrees F., in the first case there will have to be given up by each pound of water 144 B.t.u. to the surrounding air or other medium, which does not affect the temperature in any way, but which must be given up before the water can turn to ice. Similarly when ice is turned to water, before the change can take place, the ice must absorb 144 B.t.u. from the surrounding body which has no effect on its temperature, before it can change its state. Boiling water at atmospheric pressure has a temperature of 212 degrees, and in order for the water to become steam at the same pressure and temperature each pound of water must absorb 966 heat units which in no way affects its temperature, but is necessary in order to change its state.

Latent heat alters with the pressure and temperature of steam and water and the latent heat of other volatile liquids is different for each one of them, but there are accurate tables available which give the latent heats and boiling points of any liquid in common use.

It is the high latent heat, or capacity of storing heat, that makes steam so well available for the purposes of turning heat into mechanical work, in the steam engine, turbine, etc. Its high latent heat would be of advantage in using it for a refrigerating medium, only that it is offset by its high boiling point which makes it unsuitable.

What is required for a successful refrigerating medium, or working fluid for a refrigerating machine, is a liquid which will volatilize at a low temperature, while still possessing a comparatively high latent heat, and is capable of being liquefied again at a comparatively low pressure. The reasons for this are easily seen. It is by extracting heat from the medium surrounding the refrigerator that the liquid is turned into a gas. Now the higher the latent heat of the refrigerating fluid the more heat will be extracted from the surrounding body per pound of refrigerating fluid. On the other hand, if the boiling point of the refrigerating medium is high, the temperature of the surrounding body would have to be still higher for an exchange of heat to take place, therefore it is imperative that refrigerating medium must have a boiling

point lower than the lowest temperature that is required in the body to be cooled. The question of being liquefiable at a comparatively low pressure is an important one, as otherwise it means that the machine will have to be enormously heavy in build and correspondingly expensive.

It can readily be seen that for the above requirements only a medium possessing low boiling point and high latent heat is available. Fortunately we have several of these in commercial use. Probably the most generally used is ammonia. Ammonia has, at atmospheric pressure, a boiling point at —26.4 F. or 26.4 degrees below zero. Its latent heat at that pressure and temperature is 543 B.t.u. so that in order to vaporize one pound of saturated ammonia at atmospheric pressure the surrounding body must give up 543 B.t.u.

Carbonic acid gas, which is also used to some extent, and very much in marine refrigerating machines, requires the use of much higher pressure than ammonia. For instance, the boiling point of carbonic acid gas when at a pressure of 183 pounds is 30 degrees below zero, and its latent heat at this pressure and temperature is 140. Other mediums are sulphur dioxide, or sulphurous acid, and ethyl chloride which is used to some extent in small household machines.

Types of Machines

The various types of machines consist of cold air, compression and absorption machines. The cold air machine is practically out of use as it requires a large amount of machinery and takes up considerable room. Its construction is briefly as follows: There is a steam cylinder, and two air cylinders, with the necessary pipes for carrying the cold air to the rooms to be refrigerated, and pipes for circulating cold water. Air is drawn into a small cylinder, or in other words is driven by the steam cylinder. It is compressed in this cylinder, which is water jacketed to carry off the heat caused by compression. From the small cylinder it is discharged to a larger cylinder, and is allowed to do work on the piston of this cylinder, thus giving up heat and reducing its temperature. It is then discharged to the pipes which circulate round the room to be cooled, and the heat of the room is absorbed by the cold air, which is then drawn back into the cylinder to be recompressed. Thus we have the cycle again. Work is done upon a refrigerating medium, which appears in the medium in the form of heat. This heat is rejected partially by the circulating water, and then the intrinsic or latent heat as well as the remainder of the sensible heat is given up by performing work on a piston. The medium then circulating in contact with the body to be cooled absorbs heat from it, which replaces the latent heat in the refrigerating medium, and thus becomes lowered in temperature. The refrigerating medium has now made up the latent heat, but is at much lower temperature than it was formerly. In going through the cycle again, work is done upon it, which brings its temperature up again, and the cycle is repeated. In a perfect refrigerating machine the work done on the refrigerating medium and appearing as heat, which is rejected to the condensing water, should be exactly balanced by the heat units drawn from the body that is being cooled, but of course no machine effects this result exactly. The closer it comes to it the higher its efficiency.

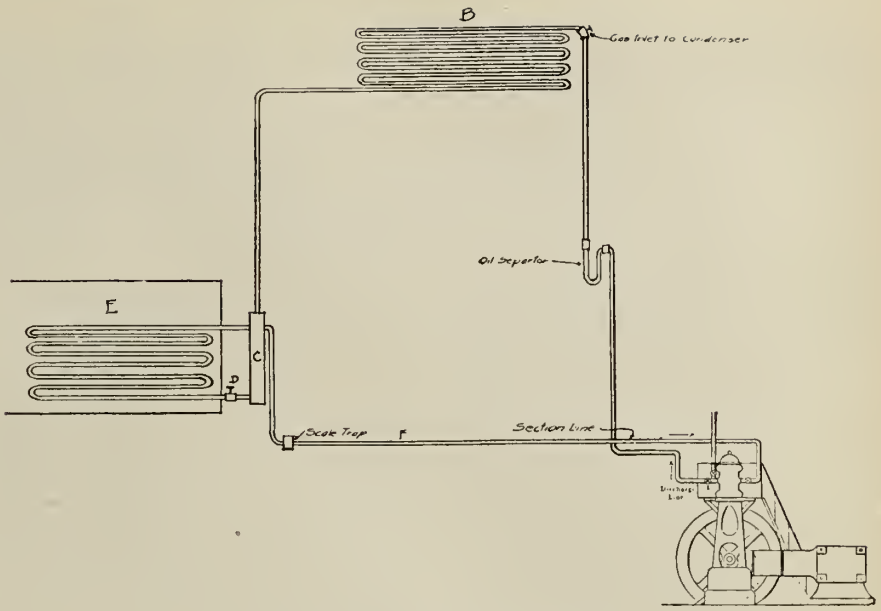


DIAGRAM OF COMPRESSION SYSTEM.

The Compression System

The compression system using a volatile liquid is based on the same principle. A charge of ammonia gas at low pressure and temperature is drawn into the compressor cylinder, and is then compressed by the piston of the compressor. Being compressed to a smaller volume, it has work done upon it, and this work appears as heat, the temperature of the gas being very much increased. Part of this increased temperature is carried off by the water jacket surrounding the compressor, or else by the vaporization of a small amount of liquid in the cylinder, but the gas is discharged from the compressor to the condenser at a higher temperature than that of saturation, which prevents it liquefying. In passing through the condenser this extra or superheat is given up, and also the latent heat which was in the gas, leaving it at the bottom of the condenser in the form of a liquid again, at high pressure, and a temperature about that of the condensing water discharge. From there it is passed through a small regulating or expansion valve into the evaporator, or direct into coils in the room to be cooled. It immediately expands, and if there were no heat available to turn it into a gas would remain as a liquid at low temperature. However, the surrounding medium contains heat which the refrigerant absorbs, thus enabling it to become a gas again, and in doing so reducing the temperature of the surrounding body. Thus we have again work done on a medium producing heat. This heat, which is shown in increased temperature, is given up to the circulation water, and besides this the latent heat of the gas is also given up to the condensing water, allowing the gas to become a liquid. This latent heat is taken out of the body to be cooled, reducing its temperature, and the refrigerating medium goes back to the compressor with its latent heat returned, but its temperature some 10 degrees lower than the body it is cooling. The temperature is again brought up in the compressor, and the cycles repeated.

The Absorption Machine

In the absorption machine there is no compressor used, but the same principle applies. The machine consists in general of a generator or distiller which is a cylindrical tank containing a set of steam coils and a quantity of liquid ammonia. There is also a condenser, and an evaporator, also an absorber. There are other appliances known as the exchanger and rectifier, and an analyser. The operation in general is as follows: Steam is applied to the coils in the generator, with the result that the liquid ammonia boils, and the ammonia gas is separated from the liquid, rising up precisely as steam does from water. It is under a pressure of about 100 pounds when leaving the generator. For the moment neglecting the intermediate apparatus, we may say it passes to the condenser, where it is reduced in temperature sufficiently to allow it to condense. It then passes to the evaporator or to the expansion coils through an ordinary regulating valve, where it again is transformed into a gas at low pressure and temperature, absorbing heat in

order to make the change of state. It passes then into an absorber, where the gas coming from the evaporator meets with weak liquor which is blown into the absorber from the bottom of the generator. This weak liquor absorbs the ammonia gas, and is thus turned into saturated ammonia liquid, and the pump then takes it from the absorber and returns it to the generator, where it is again boiled. The analyser is a tower in which are contained several cast iron plates or pans one above the other. The hot gas rising from the generator strikes the under side of these pans and heats them up. The rich liquor coming from the absorber comes in the top of the analyser and flows over these pans, thus being heated up to nearly the temperature of the outgoing gas. This serves the double purpose of heating the incoming rich liquor and cooling the outgoing hot gas. The hot gas on its way out contains a certain amount of water vapor, and after leaving the analyser it passes through the rectifier. This is merely a chamber containing coils through which the weak liquor coming from the absorber may circulate or a cold water circulation may be used. Its object is to cool the hot gas sufficiently to allow the water content to be condensed and returned to the generator. The weak liquid from the bottom of the generator which is blown by pressure over into the absorber passes on its way through the exchanger, which is simply a tank containing coils. The hot weak liquor in these coils is surrounded by the cool rich liquor coming from the absorber, and the temperature of the strong liquor is raised and the hot weak liquor is cooled. These are refinements for the better working of the system but the broad principles remain the same. The still and condenser constitute the high pressure side, while the evaporator and absorber constitute the low pressure side. The cycle is as follows: Heat is supplied to the ammonia liquid, which turns it into a gas, raising its pressure and temperature. The gas passes to the condenser where its sensible and latent heat are rejected to the circulating water, and it goes through the regulating valve to the evaporator or refrigerator in the form of a liquid at low pressure and about atmospheric temperature. Here it is again turned into a gas by the surrounding body, absorbing heat from it in doing so, and returns to the absorber in the form of a gas at low temperature and pressure. In the absorber it meets the weak liquor from the generator, which absorbs the gas and becomes saturated, and is then pumped back into the generator to repeat the cycle.

Brine Circulation and Direct Expansion

The difference between brine circulation and direct expansion is in the method for cooling the room or contents of a room. In the brine system the refrigerant is passed through a tank which contains a quantity of calcium chloride and water in solution, of sufficient density to prevent freezing. The solution in the tank supplies the heat to boil the liquid into a gas, and is then at its reduced temperature passed through the room to be cooled. Here it absorbs heat from the room to replace that which it has given up to the gas, and is returned to the evaporator to again give up this heat and be circulated once more. With the direct expansion system no brine is employed. The ammonia passes from the condenser to the ammonia coils which are situated in the room to be cooled, and the heat necessary to transform it into a gas is taken direct from the air of the room and its contents.

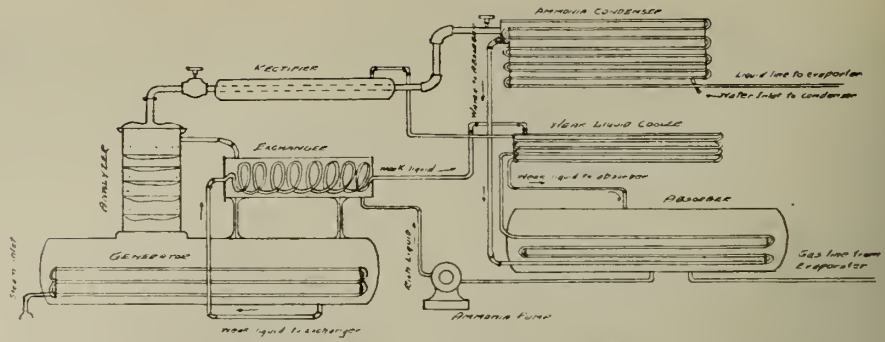

DIAGRAM OF ABSORPTION SYSTEM.

Conclusion

This article has dealt in a general way with the principles and practice of refrigeration, and is meant simply to give a general idea to those who have not studied the subject. It does not go into details, as this would take up too much space, but it should encourage those who want to understand this subject to look into more complete literature on the subject. The information contained here will be found useful for those contemplating taking the examinations for graded certificates.

TO INVESTIGATE U.S. LIGNITES

Dr. Erich W. Zimmerman, professor of commerce of the James Millikin University, Decatur, Ill., has been detailed by the United States Bureau of Mines to make an investigation regarding the fuel situation in the Dakotas, Minnesota and nearby states with a view to determining the extent to which carbonized lignite might find a market in that general region. Dr. Zimmerman will make a close study of the fuel supplies available in the northwest, the characteristics of these fuels and the prices obtained therefor.

The detailing of Dr. Zimmerman to this work marks a further advance in the investigation regarding the possibilities of increased utilization of the northwestern lignites for which the sum of $100,000 was appropriated by the sixty-fifth congress. Recently W. W. Odell, fuel engineer of the Bureau of Mines, was sent to Montreal and Ottawa for the purpose of effecting an exchange of information with the Canadian Government relative to the technical problems involved in the carbonization of lignite. The Dominion Government has for some years been working upon the problem of the utilization of the vast stores of lignite in the Western provinces and has spent several hundred thousand dollars in these investigations. The visit of Mr. Odell resulted in the obtaining of much valuable information. The Bureau of Mines is now assured that the lignites of the northwestern states can be converted into a high-grade smokeless fuel, the process yielding quantities of gas, ammonia, oils and tars as valuable by-products. With the practicability of the carbonization process assured, it remains only to consider the economic side of the situation, and to determine whether the carbonized lignite can compete with the high-grade coals of the central Mississippi and Ohio valleys, which are now being shipped by long freight hauls into the northwest.

The nation's coal resources of all ranks total 3,553,637,100,000 minable tons of 2,000 pounds, 1,051,290,000,000 tons, or nearly one-third, being lignite. Of this lignite 964,424,000,000 tons is in North and South Dakota and northwestern Montana, approximately 23,000,000,000 tons in Texas, 7,404,300,000 tons in Alaska and relatively smaller quantities in several of the other western and southern states.

OBITUARY

The death occurred last week in Galt of Jos. Flaherty, who for the past thirty-seven years has been chief engineer for the Canadian Cereal and Flour Mills, Ltd., of Galt.

In the death of Mr. Flaherty the Canadian Cereal and Flour Mills lost a good engineer and the community a good citizen who was respected and admired by all.

Mr. Flaherty was on duty till the day preceding his death, which was from natural causes.

A Treatise on Modern Refrigeration*

Definition of the Law of Thermo Dynamics—Comparison of Rankin Cycle—Refrigerating Mediums—Use of Refrigeration—A Discussion of Various Styles of Insulation in Use

By PROFESSOR J. WEMYSS ANDERSON

THE author in recent years has written a number of papers dealing with refrigeration, the chief of which have been read before the Institution of Mechanical Engineers, the Cold Storage and Ice Association, and the Liverpool Engineering Society, and the author would refer members in quest of detail to those papers.

The object of the present paper is:

a. To stimulate the interest of the mechanical engineer with good knowledge of heat engine work in the general question of low temperatures, and to show him that his knowledge of fundamentals will carry him a long way—a very long way—in the study of refrigeration.

b. To appeal for a wider theoretical and technical knowledge of the reversed heat engine, and, as a direct consequence, for wider applications of low temperatures to industries.

c. To appeal, in a university city, for post-graduate instruction and research in the subject, and for funds to carry out the same in your district.

Refrigeration

Refrigeration may be defined as a process for making a quantity of matter colder than its surroundings.

The laws of thermodynamics, which, of course, permit of refrigeration, have been expressed in various ways, but the most suitable for the subject under discussion are:

1st Law. Heat and mechanical energy are mutually convertible, and Joules' equivalent gives the rate of exchange.

2nd Law. It is impossible for a self-acting machine, unaided by any external agency, to convey heat from one body to another at higher temperature. (Clausius.)

The second law admits of the possibility of making bodies colder than their surroundings, but states that an expenditure of energy is necessary.

In modern refrigeration on a commercial scale mechanical energy is most usually employed — generally obtained by the expenditure of heat in a heat engine, which in turn drives a vapor compression refrigerating machine. Heat, however, can be directly utilized in an absorption refrigerating machine, and it would appear that a development of this style would make for greater efficiency.

It is, therefore, clear, by combining the two laws of thermo dynamics, that the effects required in refrigeration, i.e., extraction of heat, can be produced by the expenditure of heat in a suitable machine or combination of machines. The over-all efficiency of such a combination would be given by the ratio of the heat expended to the heat extracted.

For the conditions that obtain in, say, cold-storage work, the ratio, for the refrigerating machine only, is about 1 to 5, i.e., one thermal unit expended will extract five thermal units from the body cooled. This "efficiency," being greater than unity, is generally termed "coefficient of performance." The five thermal units so extracted cannot, by any possible means, be converted into an efficient source of mechanical energy, as it constitutes what is known as "unavailable heat." The one thermal unit expended is generally the heat equivalent of available energy.

Thus, the energy in a torrent of ice-cold water could, by the combined use of a water turbine and a refrigerating machine, be made the source of a very efficient warming appliance, but by no means could the heat equivalent of the energy in the torrent be made available, efficiently, as a source of heat in a heat engine.

Kelvin, in 1852, pointed out the possibility of a refrigerating machine being economically employed for warming purposes, but he also enunciated what has just been stated, re the torrent of water, in another form: "It is impossible by means of inanimate material agency to derive mechanical effect from any portion of matter by cooling it below the temperature of surrounding objects." As a further example of this method of expressing the second law, it can be stated at once that liquid air cannot, efficiently, be employed as a source of mechanical energy.

	Steam Engine.	Vapor-Compression Machine.
Flow of Heat.	Down.	Up.
$T_1 p_1$	BOILER. — High temperature heat, quantity H_1 transferred from fuel to the water forming steam at $T_1 p_1$.	CONDENSER.—High temperature vapor at $T_1 p_1$ condensed into liquid. Heat rejected H_1.
	CYLINDER —Part of heat, H_1 in the steam converted into mechanical energy, remainder. H_2 sent into condenser at $T_2 p_2$.	COMPRESSOR. — Energy expended (AW) in compressing vapor at p_2 into vapor at p_1. Total heat sent into condenser $= H_2 + AW = H_1$.
$T_2 p_2$	CONDENSER.—Steam at $T_2 p_2$ condensed into water at $T_2 p_2$. Heat rejected $= H_2$.	EVAPORATOR.—(Refrigerator) Heat, quantity H_2, extracted from body to be cooled by means of vapor at $T_2 p_2$.
	FEED PUMP.—Energy expended in pumping water at $T_2 p_2$ back into boiler at $T_1 p_1$.	REGULATING OR EXPANSION VALVE. — Liquid from condenser at $T_1 p_1$ allowed to pass freely into evaporator at $T_2 p_2$. Energy not utilized.
Efficiency.	Heat utilized $= H_1 - H_2$. Heat expended $= H_1$. Ratio of heat expended to heat utilized $= \frac{H_1 - H_2}{H_1} = \frac{T_1 - T_2}{T_1}$	$H_2 + AW = H_1$ (from above) $\therefore$ $AW = H_1 - H_2$ = heat expended. Ratio of heat extracted (H_2) to heat expended $= \frac{H_2}{H_1 - H_2} = \frac{T_2}{T_1 - T_2}$

*Transactions of the Institute of Shipbuilders and Engineers in Scotland.

The refrigerating machine is a heat pump, and, as such, is the reverse of a heat engine. The vapor-compression machine in common use to-day is the reverse of the steam engine working on the Rankin cycle, and many of the researches, improvements, and discussions which have marked the progress of the steam engine can be applied with advantage to the vapor-compression machine—remembering always the question of reverse action. Thus:—

1. Range of Heat. In the steam engine the greater the range T_1, T_2, the greater the efficiency; in the refrigerating machine the smaller the range the greater the coefficient of performance.

2. Medium. The medium in the steam engine is water which under normal atmospheric conditions is liquid, and one of the main objects in the whole operation is to convert this liquid at T_2p_2 into a vapor at T_1p_1. The medium in the refrigerating machine under normal conditions is a vapor at T_2p_2, and one of the main operations is to convert this vapor into a liquid at T_1p_1.

3. Feed. The hotter the water forming the feed into the boiler the greater the efficiency, and any available heating effect should be utilized. The colder the feed of the liquid refrigerant into the evaporator in the refrigerating machine the greater the coefficient of performance. Mr. G. W. Daniels,* M.Eng., has shown that an auxiliary refrigerator used to reduce the temperature of the feed in a carbonic anhydride machine cooling at —50 degrees C. resulted in an increased refrigerating effect at 75 per cent., with an increase in horsepower (including that required for the auxiliary machine) of about 27 per cent., while the overall saving was 27 per cent.

4. Condensation and Vaporization. Bearing in mind the statements under 2, it is important that the steam should remain steam while operating in the engine, any water formed at any stage should be rejected at once to the hotwell, its function being over, and its presence detrimental. Likewise, any vapor formed, at any stage, in the refrigerating machine should be transferred to the condenser as soon as possible, as its function is over. In passing the regulating valve, some of the liquid vaporizes to cool itself from T_1 to T_2. This vapor represents a definite loss, and anything that can be done to reduce this loss is, of course, a gain. Cooling the feed, as mentioned under 3, is one way, and is really the reverse of superheating the steam supply, which not only increases T_1, but reduces condensation in the steam engine. Another method of reducing the loss by vaporization on passing the regulating valve is employed by Mr. Voorhees in his "multiple effect" CO_2 refrigerating machine.*

*"Some Recent Developments in the Theory and Practice of Refrigerating Machines." — Trans. Liverpool Engineering Society, 8th January, 1919.

5. In the cylinder of the steam engine any means such as lagging and steam jacketing, that will keep the steam from condensing and prevent heat "leaking out," has been advocated and discussed at length. In the refrigerating compressor, anything that can be done to prevent heat "leaking in," and actually encouraging heat to "leak out" from the compressor, and thus prevent superheating, should be done. Water jacketing under some conditions is a great advantage, heat being removed thereby by the water. Unaflow compressors are also employed, which keep the cold vapor at one end and the compressed hot vapor at the other.

The above five reverse parallel cases suffice to illustrate the point raised, and steam engineers taking up refrigeration should bear the "reverse" action in mind —they will soon find their knowledge of great value. Research on the points enumerated is much required in refrigeration, as nothing like the work has been done in this section corresponding to the steam engine side.

Refrigerants

Water has never been seriously challenged as the medium in the vapor-expansion heat engine, but in the vapor-compression heat pump many media have been tried, but carbonic anhydride (CO_2) and anhydrous ammonia (NH_3) hold the field, while sulphurous anhydride (SO_2) is also used.

Ethyl chloride (C_2H_5Cl) is now being used with a turbo-compressor and this machine corresponds to the reverse of a steam turbine.

The chief characteristics of the principal refrigerants are given in the following table:

	Temp. F.	Abs. pressure Lbs. per square inch.	Specific Volume. Liquid.	Specific Volume. Vapor.	Heat Content. B.Th.U. Lbs. Liquid.	Heat Content. B.Th.U. Lbs. Vapor.
CO_2	0°	308	0.016	0.20	—13.5	103.0
	75°	904	0.022	0.07	+31.5	88.3
NH_3	0°	30	0.024	9.2	—33.7	538.5
	75°	141	0.027	2.1	47.8	556.0
SO_2	0°	10	0.01	7.1	— 9.9	152.0
	75°	54	0.01	1.5	14.4	162.0
C_2H_5Cl	—4°	3.6	0.016	21.3	—15.4	163.0
	77°	22.94	0.018	3.84	19.2	183.5

These figures indicated at once that the refrigeration per unit of compressor volume was relatively great for CO_2 (i.e., small compressor), medium for NH_3, and small for SO_2 (i.e., largest compressor). Against these facts, the working pressures and pressure difference in the CO_2 machine are very heavy, and are very light with SO_2. The heavy working pressures told against CO_2 in the early years, but more experience and high-class workmanship have lately favored this refrigerant. Reliable tests and research are greatly needed to indicate which is the more efficient machine, CO_2 or NH_3, and in what ratio.

The author, in 1912,* had written: "In his own opinion, a captain who went into action with his refrigerating machine charged, either CO_2 or NH_3, committed a grave error of judgment—with NH_3 for the reasons just given (appalling effect of a burst ammonia pipe on the crew), and CO_2 because of the risk of asphyxiating the men below decks." This advice had not been followed in the late war, until our warships had been in action and had proved the necessity of blowing off the charge, when orders were issued accordingly.

With reasonable precautions—on land and on sea—no danger need be feared from the use of either refrigerant. The same type of precautions that prevented steam, products of combustion, and ash dust reaching the passengers or crew (or both) at sea is all that is necessary to dismiss any discussion as to the better refrigerant to use on ship board.

With respect to the future and immediate progress, while ethyl chloride may find favor by virtue of its rotary compressor—particularly for small plants—the author is of the opinion that quick-revolution vertical compressors, driven either electrically or by means of multicylinder vertical hot-bulb oil-engines, will prove the most satisfactory line of development. Many refrigerating engineers will not doubt favor a quick-revolution driving engine coupled by reduction gear to a slow-revolution compressor.

Use of Refrigeration

There are many important industries and branches of engineering that would benefit by the greater use of refrigeration—civil, mining, and electrical engineering, chemical, rubber, chocolate, margarine, and dye works, dairies, breweries, and distilleries, while the much-needed public up-to-date abattoirs would have chilling rooms as a first necessity. The great cities are fairly well supplied with cold stores, but the rural and urban districts should, also, from an economic point of view, be abundantly supplied with cold-storage facilities. In such developments the use of electrical methods for the transmission and utilization of energy should be carefully noted in con-

*See Sir Wilfred Stokes— Proc. Inst. of Mechanical Engineers, 1912, parts 3-4, p. 1130.

junction with refrigeration, as the latter requires more energy in summer than in winter, and could easily be made the means of devising a type of load that would be most acceptable to the electrical engineer.

Coal Storage and Transport. The greatest use of refrigeration at the moment is for the storage and transport of perishable produce. A cold store is nothing more nor less than a warehouse, where the air is "conditioned" to suit the produce stored—such as meat, ham, bacon, fish, poultry, game, rabbits, milk, butter, cheese, margarine, eggs, fruit, vegetables, wines, and beer.

The pioneer cold-storage owners built their stores and waited for the merchant to rent so much cubic feet of space. The successful cold-storage companies of today are traders in chilled or frozen produce who keep their merchandise to suit their customers' convenience. This, in turn, has resulted in regular lines or even fleets of steamers being built for the special purpose of carrying refrigerated produce, and run by cold-storage companies. Thus it is that the harvests of the world are equalized, and the produce of the antipodes brought in excellent condition to our very doors.

The engineer has been chiefly responsible for this success, which, in the main, has been worked out by the trial and error system. Now, however, the Department of Scientific and Industrial Research has a food investigation board (originally established less than three years ago as a cold storage research board) at work, and it is confidentially to be expected that the rule-of-thumb methods now obtaining in cold storage will be replaced by rules framed, as the name of the department suggests, by a right combination of scientific and industrial effort.

It would be useless to deny that cold-stored food is the success that nature's own method of preservation merits—it neither tastes nor looks, for the greater part, like the fresh product. The author, after long experience, is of the definite opinion that, with reasonable (i.e., commercially possible) care, most foods would improve with low temperature treatment.

Milk, intended by nature only for feeding the very young, and even then by passing direct from the mother to the offspring, is perhaps one of the most unstable foods in general use. Yet, by the aid of refrigeration and common-sense hygiene, it can be kept perfectly sweet for weeks.

Fish, another very unstable food, can be kept in the best condition by preventing bruising and by the aid of refrigeration. It cannot be pleasant for a Scotsman to know that before the war 25 per cent. of the Aberdeen fish reaching London was from German fishing boats. Why? Because up-to-date commonsense and low temperatures went hand in hand. It is not suggested that either milk or fish should be frozen — only chilled.

The fish problem of Great Britain will not be met by freezing, but by careful handling, chilling (careful icing probably the best), and rapid transport. The herring, for instance, moves around Great Britain in a most leisurely fashion, producing gluts at fishing centres at stated and regular intervals. The problem of getting these valuable fish into the industrial centres could easily be met by herring trains, which would follow the movements of the fish, and thus meet and ease the gluts. The Ministry of Transport could help in a matter of this kind, and refrigeration would be a great aid.

Insulation

In the construction of cold storages and in the insulation of ships' holds most curious mistakes are still made (in books and in practice) on the assumption that the sole object is to "keep the cold in," whereas the true problem is to keep the heat out, and anything that can be done to dam off the influx of heat is to the good. Thus a warehouse in the form of a cube, where the weatherproof and airproof walls do not carry any of the weight of the stored material (i.e., girders not built into the walls), and are thoroughly insulated without break from top to bottom, are the first essentials of a good cold store. A properly constructed roof or ceiling and basement floor being assumed as part of the "walls" of the cube, it only remains to be said that, from a constructive point of view, openings at the top only for the goods complete the requirements.

The subject of insulation is a very much discussed one, but Prof. Thornton, who has made a special study of the subject of insulation for cold-storage work, has made a great step forward in the matter of the conduction of heat (perhaps "resistance to heat flow" would be a better term) in his paper in the "Philosophical Magazine." The following table (extract) is there given:

Material.	Density p.	Elasticity, E. 10^{-11}	Velocity Sound V. cm. sec. 10^{-5}	Epx 10^{-11}	V^2p^2x 10^{-11}	Thermal Conductivity, k, in Calories observed.
Graphite	2.3	5.25	4.65	12.1	11.5	12.0
Marble	2.7	2.6	3.10	7.0	7.0	7.1
Mahogany, Honduras	.62	.88	3.7	0.54	0.52	0.5
Deal	.5	.9	4.2	0.45	0.44	0.4
Ice	.91	.28	1.74	0.25	0.25	0.22
Paraffin Wax	.91	.151	1.30	0.137	0.14	0.141
V. India-rubber	1.02	.05	.07 .7	0.05	0.0005 0.05	0.45
Cork	0.24	.0055	.48	0.0013	0.0013	0.13

"It was not to be expected that a quasi-solid such as india-rubber should conform to the rule. Its velocity of sound, calculated from E and p $0.7.10^5$, centimetres a second; the observed value is $0.07.10^5$. In either case the values of Ep or V^2p^2 are of a lower order than the conductively observed by Lees, though the numeral is the name."

These results are of the utmost importance to those interested in cold storage work, and point to the possibility of definite laws being formulated respecting the transfer of heat, which would hold good for all temperatures and all temperature differences within changes of state.

Prof. Thornton concludes:

"The object of the present note is to direct attention to the above relations between k, E, p, and V, which must be explained by any theory of conduction in non-metallic solids. The chief practical qualification of a material as a heat insulator is that it should be light and inelastic."

It is not to be supposed that with definite laws of the transmission of heat, and a thorough investigation of the conditions obtaining generally in cold-storage work, the problems of the refrigerating engineer would be solved. The electrical engineer has very definite knowledge of the various insulators he employs, and this, to a certain degree, has led to a standardization in the most ordinary cases. Yet a variety of circumstances leads him to vary his practice to suit ever varying conditions, and he is, of course, able to test his insulation before the current is laid on, and during the lifetime of the installation. The expert refrigerating engineer does, of course, vary his practice, but in the majority of cases the want of definite direction leads to rule-of-thumb practices applied without the least discrimination.

Thus, in a cold store, where trouble had been experienced with the insulation, and recently brought to the notice of the author, it was found that the southeast corner chambers, with two exposed walls, had exactly the same insulation as the north chambers, with one exposed wall. The insulation contractor concerned stated this was the usual practice. It has not been the author's practice.

The main conditions that determine the thickness and type of insulation are:—

a. The cubic capacity, use, and shape of the stores. Thus, a store of 50,000 cubic feet, rectangular in plan, intended for freezing produce, should have a better insulation than a store of 750,000 cubic feet, with a square section intending for storing frozen produce. Ships' holds present a number of possible combinations—next to boilers, below sea level (water-washed surfaces), above sea level (sun-heated surfaces), and the possibility of the hold being submerged.

b. The position and construction of the wall. A well-constructed 14-inch brick wall on a north side would require much less insulation than a reinforced concrete wall on a south side of a store. Concrete walls require much care and attention, and every effort should be made to obtain a non-porous exterior finish, with three or four coats of bitumen on the inside before any type of insulation is fitted.

The steel walls of a ship present an unequalled condition for allowing heat to "leak in," and it is only now that careful differentiation is being understood, but nevertheless too much rule-of-thumb still prevails. During the war it was found that beef in the top corner of a hold at the ship's side was not in good condition, and a "ribbon" of insulation, about four feet wide, was placed fore and aft on the top, inside the chamber, next to the ship's side. This, no doubt, under the conditions, was good practice, and with timber or ferro-concrete beams would have been sound practice on land, but the succeeding trip showed that the trouble had only been partially solved, inasmuch as while the beef in the corner near the ship's side was sound, the meat nearer the centre line, and just outside the ribbon, was a bit off color—i.e., the heat meeting additional resistance, in the shape of the ribbon, travelled along the beams to the region beyond the ribbon.

Again, on ship board, in chambers designed for carrying chilled beef a degree variation in temperature is a matter of moment. A ship passing through the tropics, therefore, must have an insulation quite equal to that in a ship designed to carry frozen goods. Thus, particularly in ship work, the conditions a and b are interdependent.

c. Material and labor and local conditions.

Insulation requires very great care, skill and experience for successful construction. If, say, charcoal or slag wool is used, the greatest care is required to make the sheathing airproof and waterproof. On ship board, with the thin steel work, scamping would lead to heat leaks that might in turn lead to the loss of thousands and thousands of pounds. It is easy to specify an efficient insulation in this country; abroad, however, the difficulties with either or both materials and labor might reduce the value of the same specification to a minus quantity.

Thus, in Japan, say, it might be quite good policy to use rice husks specially treated, because the skilled labor available is good, and careful supervision would ensure air, water, and vermin-proof casings.

Local considerations are most important. If trouble is to be expected from, say, white ants or rats, then tinned sheets must be introduced if boards are used as a sheathing. With the personal equation so prominent, it is not surprising that baked cork slabs built up by means of hot washes of bitumen, and finished off on the inside with a layer of special cement, have become so popular of late. It is not that cork is a better non-conductor than either slag wool or flake charcoal—it is that the construction approximates so closely to the ideal air and water-proofness.

Yet very serious danger lurks behind the use of cement in unskilled or inexperienced hands. Most cements are very porous, and mould and other spores are liable to collect in their millions on its surface. Cements, therefore, should be subjected to the same hygienic treatment that most careful managers insist upon in their cold stores; the surface should be carefully varnished, finished with white enamel paint, or whitewashed. The two former should be wiped over with disinfectant once a year, and the latter whitewashed every two years at least.

It must be reiterated that a large, well-constructed and insulated cold store, square in plan, offers no difficulties to the refrigerating engineer, but careful consideration of detail will keep down the first cost, and subsequent running expenses.

Education and Research

The previous portion of the paper will show that a good mechanical training, together with a sound knowledge of applied heat, is the first essential of an engineer who wishes to study the technics of low temperatures. In the United States, every engineering school of any standing has always a refrigerating laboratory attached to it. In Great Britain, there is not a single instance of such a laboratory. It is true that many laboratories have one or more refrigerating machines, but the entire absence of published research work clearly indicates that nothing of value is being done. Yet the field is very wide. Every corresponding step in the reversed cycle which has been the subject of research and discussion in the direct cycle offers ample scope for investigation.

The prejudice against frozen produce could be eliminated altogether with a better and wider scientific knowledge which would come from the researches of the bio-chemist and the bacteriologist. The transport by rail and road would also be greatly facilitated by a wider knowledge, while a proper understanding of the subject of food values would, without doubt, show that in the majority of cases food was often kept in cold stor until it was quite unfit for human con sumption.

A self-digestive action is always go ing on in meat at the temperatures i the ordinary cold stores, and a preserva tion of structure and absence of sme is no criterion of its soundness for ea ing purposes. It is true that the Foo Investigation Board has now much this work in hand, but it must rema for our universities and colleges to the necessary educational work, and firs hand knowledge of research is an esse tial of every teacher.

The latest report of the Departme of Scientific and Industrial Resear showed that the Government had agre to spend £30,000 for the erection of special cold-storage laboratory at Ca bridge. Glasgow and all other univer ties should be similarly equipped. Her in lies an opportunity for your citize to benefit science and the populace one stroke.

The Conveyors Corporation of Am ica, Chicago and New York, ta pleasure in announcing the appointme of Robert B. M. Wilson as sales engine of the Chicago district. With him w be associated as an assistant E. Wolfe. Headquarters will be ma tained in the corporation's main off at 326 West Madison Street.

Mr. Wilson has had a well-round experience in industrial engineeri Ten years were devoted to railroad co struction and maintenance, six of wh were spent in the republic of Mexi For five years he was special represen tive of a nationally known manuf turer, working among large industri plants in the central states. Since 19 he has been an associate member of e American Society of Civil Engineers.

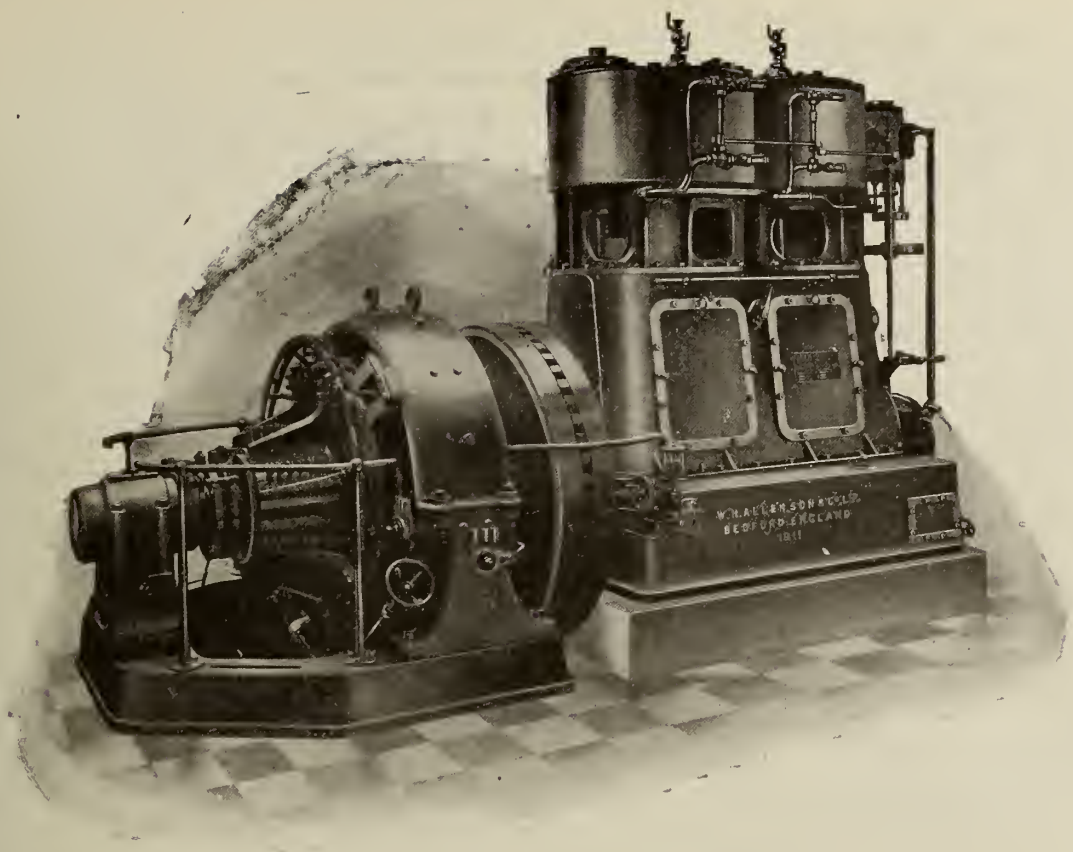
During the world war he spent e larger part of his twenty-seven mon of service in France, receiving his di charge as major in the 311th Engine

Since the war he has been a sa engineer with the Conveyors Corpo tion, being located in Indiana sales t ritory.

Mr. Wolfe has been connected w the Conveyors Corporation for sev years in a sales capacity. He has considerable experience in conveyor gineering and has aided in designing conveying equipment of some of foremost plants in the Chicago distr

The Conveyors Corporation manuf tures a complete line of coal and h handling equipment.

Estimates are being prepared for new arena and ice plant to be erec at Ottawa shortly. The arena will be situated at the corner of King Edw d Avenue and York Street and will ha e a cold storage plant in connection wit t



Allen "Open" and "Enclosed" Engines

Allen "Open" and "Enclosed" engines are British built and embody all the best elements of engineering practice. They represent 40 years of experience in the design, manufacture and application of these classes of engines.

Their advantages comprise automatic lubrication, simplicity, silent running, minimum of attention, durability, accessibility, efficient governing, compactness, maintained efficiency, low cost, low running expense, low steam consumption, suitability for superheated steam, and interchangeability of parts.

These engines are eminently suitable for all purposes where direct, rope, belt or gear driving is required.

Our nearest branch will be glad to send detailed specifications.

Central Heating Plants

WE recently commented editorially on the advantages of the central heating plant from a general point of view. Since then we have had an opportunity of inspecting what is probably the largest central heating plant on the continent.

This plant, which will be fully described and illustrated in our next issue, is in connection with the new Parliament Buildings in Ottawa. It heats no less than nine buildings, the furthest from the plant being nearly one mile away. It has justified its existence by the savings it has made in its first year of operation and in our opinion it would be a better proposition still if operated as both a lighting and heating plant.

The pleasing feature is that the plant is to a large extent the product of Canadians. The consulting engineer who designed it and the contractors who carried it out and a large part of the equipment put into it are products of Canada.

There is no reason why this should not apply to more plants if Canadians would get away from the idea that they must go to the States for consulting engineers and architects. There is plenty of good material right in Canada as this plant so well testifies.

Refrigeration and Our Daily Needs

IT is perhaps not generally recognized, even among engineers, what a large part the production of cold by artificial means plays in our daily lives.

The milk we take in from our doorsteps in the early morning has been kept cool in its journey from the farm by refrigerated cars. These cars are cooled by blocks of ice which have been in many cases produced artificially. In the great city dairy, after the milk has been pasteurized, it is cooled down again by circulating in a tank which is cooled by the brine from a refrigerating machine. The cattle that come from Ontario farms are slaughtered in the city and the carcasses are kept sweet and wholesome until they are distributed in rooms chilled to nearly freezing point by mechanical means. Food that is produced in abundance at one season of the year can be kept in good condition for months, so that the supply will be available over the whole year. Many people think that this feature is the cause of high prices, but looking at the question broadly, one is forced to the conclusion that it is on the whole a wonderful benefit to humanity.

The comfort of those who travel at sea is vastly enhanced by the use of cold storage on the ship, while thousands of tons of frozen beef and mutton are carried from continent to continent in refrigerated holds of ships.

Minor luxuries, like candies, are likewise indebted to the refrigerating machine. Our picture shows and theatres are made comfortable and cool on the hottest days of summer by this beneficial agency. It even contributes its quota to sp[ort], by producing the ice that our fickle climate refuses us w[hen] we have every right to expect it.

One might enumerate many other things refrigeration [ac]complishes and its share in the manufacture of T.N.T. dur[ing] the war alone entitles it to a high place in our regard. [All] these wonderful achievements at so low a cost have been m[ade] possible first by the researches of those able scientists [who] labored so patiently to find the relation between heat [and] work, and who first discovered what heat really was. Foll[ow]ing them came the practical mechanical engineer who produ[ced] the necessary mechanism to apply the scientific laws and t[hey] placed their machines in the hands of the operating engin[eer]. On his ability and knowledge in the last analysis depends [the] success of any refrigerating machine and it should be the [aim] of every stationary engineer to acquire a knowledge of [the] principles of refrigeration at least equal to his knowledg[e] the steam engine.

More and more in the future will the stationary engi[ne] have to expand and this is one of the most important directi[on]s

Our Question Box 8

THE SECRET'S OUT

N. White, a boiler inspector on the staff of the Boiler Inspection & Insurance Co., has the following story at the expense of Power House. "Some months ago," said Mr. White, "I received instructions to inspect a boiler in a sawmill in the northern part of the province. I had quite a time finding the place, but after some little trouble came across it all right. It looked as though it had been built one hundred years ago, and was ready to fall to pieces. A little stagnant pond with moss-covered dead heads sticking up from the surface lay between the mill and myself, and I worked my way around it through a network of dead brush and stumps. An old man was sitting outside the mill on a pile of slabs, and he accosted me with a cheerful "Howdy?" and further inquired if I was the man who was going to inspect the boiler. Having answered in the affirmative, the old gentleman conducted me into the boiler room, where he introduced me to a young man, his son John. Answering some questions of the old man, I remarked that I would have to make some calculations. The young man looked up at this, and informed me he could give me all the necessary information and figure out anything that was wanted. So I told him to go ahead and figure the horsepower, bursting pressure, etc., expecting that he would be stumped. Much to my surprise, he produced pencil and paper and started right in to make the necessary calculations and explained them as he went along. After I got over my surprise I asked John where he had picked up all this, but before he could reply the old gentleman said, with paternal pride, 'Why, this is where they get the information for the Power House. John hasn't been here always. He has had charge of lots of plants and written lots of articles for the Power House.' I had nothing more to say after this, and came away from that mill feeling that you never know what you will strike next."

STRAIGHTENING ROTOR SHAFT

BY JOHN S. WATTS

I read with interest the article on straightening the rotor shaft on page 32 of January 20 issue of Power House. I noted that the editor questioned the method employed, because as he expressed it, the method adopted did not relieve the internal strain in the shaft caused by the bending. He suggested that the shaft should have been heated by a blow torch, straightened by pressure, and after being annealed at a dull red heat, trued up in the lathe.

As the bending of shafts and other parts, by rough handling in transit, or by accidental over-strain in operation, is of fairly frequent occurrence, I think it would be valuable to have this matter well discussed, in an effort to determine the one best method.

That it is impossible to get a bent shaft exactly straight again, by pressing out the bend, is well known to all who have tried it, and is apparently not disputed by the editor, who specifies trueing up the shaft in the lathe, as the final operation in his criticism. To do this means turning enough off the shaft, to permit the insertion of a bush, of a practicable thickness, in the bore of the pulley, to make it fit the shaft after it is trued. The bush would have to be at least an eighth of an inch thick, thus reducing the shaft one-quarter of an inch in diameter, and seriously weakening it at the point of greatest stress.

Possibly this reduction of diameter could be made just sufficient to true up the shaft by making or purchasing a new pulley to suit, but as these motor pulleys are finished all over and balanced, on account of the high speeds they run at, in nearly all cases the delay incurred in getting a new pulley with a special bore would be fatal. Experience in straightening shafts will show that in straightening out the one bend we infallibly cause another small bend, which in this case would occur in the bearing, and for a good job we would have to true up the shaft at the bearing, and so be compelled to also re-babbitt the bearing.

The main point the editor makes is that the shaft is under the permanent initial strain imposed when bent, and that this strain is not relieved by the heat of welding. In a long experience I have seen many bent parts straightened, mostly always cold, and have never seen any annealed after straightening, nor have I ever known any failure from this lack of annealing. It seems to me that practical experience proves that a slight bend which gives no indication of having been sufficient to impose a stress approaching the breaking stress, while it undoubtedly must have strained the shaft beyond the elastic limit does not actually injure the shaft permanently, as the strain in a comparatively short period of time disappears, presumably by readjustment of the molecules, to accommodate the new shape of the shaft. It takes, to my mind, as much pressure to straighten a shaft as it does to bend it, so that this bears out the above statement, within the limits of one or two bendings, of course.

If the bend is so severe as to cause cracks to show in the shaft, the strength of the shaft is obviously permanently impaired, and it would be useless to straighten it, but the bends actually met with are very seldom in this class. Unfortunately, we do not at present know much about the behavior of steel under stresses between the elastic limit and the breaking stress, but the fact that steel can be stressed beyond its elastic limit a few times and recover

Continued on page 42

Of course you don't! Such a thing would be preposterous. Yet, many concerns are doing this very thing, figuratively, when they use big, clumsy, heavy steam traps of the bucket or float type, instead of the small, highly efficient Steam Trap SARCO.

The Sarco reduces the Steam Trap to its simplest form, cutting down first cost about two-thirds, as compared with the bucket or float type of trap, by eliminating heavy castings, complicated, costly levers, gauges, stuffing boxes and packing. There is but one moving part in the

STEAM TRAP SARCO

But that is not all. The Sarco, by reason of its mechanical efficiency, functions properly, i.e., gets rid of condensate as fast as it forms, in that way saving valuable heat units. Traps of the bucket type, which allow condensate to collect in large volume, waste a corresponding number of heat units. The Sarco returns the condensate **while hot** to the hot well.

Still another advantage of the Sarco is its small size—you can install it in "close quarters," without digging pits or building platforms—an expensive proposition that adds to the already high cost of the bucket type.

Made in sizes from ⅜" up to 3", for any given pressure up to 200 lbs.

Sent on a bona fide 30 day trial, without strings. Write for full particulars and Booket J-12.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

HEATING RETURNS

Question:—Is it advisable to run returns from a heating system in a mill from the trap through the boiler blow-off? My opinion is that the mud in the boiler has a tendency to get under the check valve, thus causing it to groove.

Answer:—We think that the blow-off is a good place to deliver the discharge from the trap. It keeps the blow-off pipe clear, and there is little danger of the check being damaged when it is continually washed by the water flowing over it. If there is any objection against putting returns through the blow-off of a horizontal return tube boiler it is that this is the hottest part of the boiler. However, returns from traps are usually at the same temperature as the steam or but little below it, so there is not much objection to this practice.

* * *

SIDE PLAY ON SHAFT

Question:—A 7½ horsepower motor driving a four-ton York refrigerating machine. There is a side play of about half an inch on the shaft of compressor when running. What is the cause of this and is there any danger in running same?

Answer:—We presume that the compressor is driven from the motor by a belt, and this is probably the cause of the side play. Having the two pulleys slightly out of line will cause side play, and the same thing will occur with a belt that has not been spliced squarely. In order to have so much side play on the shaft of the compressor there must be plenty of side play in the connecting rod and guides, but even so half an inch seems a lot. Would advise you to examine the lining up of pulleys and compressor.

* * *

DEPOSIT ON COILS

Question:—What can I do to remove lime from the coils and valves of a hot water heater? The tanks have steam coils in them and the water surrounds the steam coils, the impurities in the water being deposited on the outside of the coils as the water is heated. I have tried putting a valve coated with this deposit in a solution of Gillet's lye without getting rid of the lime. I have also tried vinegar, which helped a little.

Answer:—You are having the same trouble which is met with in evaporators in marine service, which evaporate salt water and become heavily coated with scale. In these evaporators provision is made for easily removing the coils, which are then scaled by hand. It is perhaps difficult for you to do this, but if the coils are very badly coated I would suggest that you remove them and thoroughly clean them. If possible after that use a solution of soda in the water to be heated, which will tend to keep the scale in solution, and clean frequently. The deposit is probably sulphate of lime and gypsum, which is very hard, and difficult to remove when left long. A method used with evaporators where the coils are made of copper is to empty the water chamber and leave the steam on the coils. Cold water is then admitted rapidly, and the sudden contraction of the coils cracks off the scale in large lumps. However, we would not recommend that method with iron pipes, although they might stand it all right, the danger being in the fittings.

* * *

REDUCING STEAM PRESSURE

Question:—Can you tell me why there is any gain in fuel by raising the steam to 50 pounds and then reducing it to 10 pounds for heating purposes? My chief claims that the steam is superheated when expanded without doing work, but, as I see it, the heat must have been put into the steam from the coal to begin with. I can see where there are losses from such a system, such as higher first costs, more leaks, higher temperature in chimney gases, etc., besides needing a pump or injector to feed the boiler, and the services of a licensed engineer.

Answer:—There are cases where it might be of advantage to use steam of a higher pressure and reduce it at the point of delivery. For instance, in a long run of piping, where there may be considerable condensation, it would be better to have the steam carried at higher pressure, so that when it was reduced there would be re-evaporation. For instance, steam at 50 pounds pressure has a temperature of 298, and the total heat in the steam is 1,178.5 B.t.u. Steam at 10 pounds pressure has a temperature of 240 degrees and a total heat of 1,160.4. Now if steam is expanded from 50 pounds pressure to 10 pounds pressure without doing work it will have 58 degrees of extra heat in it, and a condensation in the pipe on the 50 pound side will immediately become evaporat on the low pressure side. However, you say, the original heat has to co from the coal. This principle of usi high pressure steam and then reduci it is often used to overcome condens tion difficulties, but there has to be consideration of all factors before it c be definitely decided on for any pa ticular purpose. You may rest assur that you do not get heat anywhere f nothing, and if you had ten cubic feet steam at a certain pressure and temper ture containing a definite quantity heat units, and expanded that ste without loss or gain by radiation or a other way you would still have the sa quantity of heat units whatever char might take place in volume and pr sure, so long as condensation did take place.

* * *

OIL BURNERS

Question:—Can you give me some a vice on oil burners for 12-inch boiler These are the latest type, fitted w down draft. The top draft can be clo and made to burn as an ordinary boi

Answer:—It is always necessary use refractory brick in the furnace wh burning oil. Would advise you to in touch with manufacturers of burn and get their advice as to installati Perhaps some reader of this column w has oil burners on this type of bo would help you out.

The Lakeside Bridge & Steel C North Milwaukee, Wis., have alm completed arrangements for represe tion in Canada. The company are ma facturers of steel frame structures machinery and are general engine They will be interested chiefly in sell and manufacturing the Labride handling equipment for the Canad trade.

The Fulton Iron Works Co., St. Lo U.S.A., have published a handson illustrated catalogue describing Diesel engine manufactured by the fi The booklet, after describing briefly he origin of the Diesel engine, and its working cycle, together with sc curves and tables of fuel consumptn continues with a detailed descriptiorbt the engine itself, which is well il trated.

The LABRIDE Coal Handling Equipment

Adapted for Power House Work

OUR LABRIDE Equipment is comprised of a moving bridge traveling lengthwise of the storage space and a bucket carrier traveling crosswise, similar in all respects to the movement of a traveling crane—thus every square foot of the storage space is covered with a minimum of movements and time, the most correct and economical method known in coal handling to-day.

The Outstanding Advantages of this Equipment are:—

1st—Economy. With the use of this bridge you can save 70% to 95% of your coal handling cost if you are unloading by hand, or 25% to 50% if you are now using other mechanical methods of handling. The saving per ton is greater the more coal you store.

2nd—Eliminates shut-downs due to strikes at the mines or on the railroads or from failure to receive regular commitments of coal due to transportation congestion with which we are all familiar in recent years and which generally occurs just at the time when it handicaps us the most.

3rd—Saving money by enabling you to lay in your supply of coal in the spring and summer months when coal is generally cheaper than it is in fall. This item runs into quite an amount in case of large coal users.

Coal can be unloaded from cars to the bunkers or to the storage pile. Our No. 2 bridge, shown in the illustration above, is electrically operated throughout and has a guaranteed capacity of 60 to 90 tons per hour. The cost of the electrical current is about 60c per hour, depending, of course, upon local electrical rates. The entire unloading operation is handled by two men,—one man in the cab and the other in the car cleaning out the corners.

Write us, giving the layout of your storage yard, and we will be pleased to send a sketch of the equipment adapted to your particular requirements, together with quotation.

STRAIGHTENING A ROTOR SHAFT

(Continued from page 37)

its original strength, without any treatment, is shown in actual practice. For instance, the shell plates of every boiler that ever was built are strained past their elastic limit, in rolling to shape when cold, and evidently suffer no harm from it.

Another case is that of cold twisted bars used for reinforcing concrete. This cold twisting involves stressing the bars beyond the elastic limit, and yet tests show that the twisted bar has an elastic limit at least 60 per cent. higher than the original bar, and a tensile strength about 20 per cent. higher. That cold rolled shafting is stronger than the plain shafting is well known, and other like products could be cited which prove that a material stressed only once or twice, to a point between the elastic limit and the breaking point, is no weaker than it originally was, if not indeed stronger.

In Kent's Pocket Book are cited some tests proving the truth of this, and from page 239 of the first edition I copy the following: "The common opinion that straining a metal beyond its elastic limit injures it appears to be untrue. It is not the mere straining of a metal beyond one elastic limit that injures it, but the straining, many times repeated, beyond its two elastic limits."

Finally, then, my opinion is that Mr. Quist handled the job the best way, because he got a true shaft of the original dimensions, and that the internal strains from the bending are not of any importance, if indeed they exist at all.

W. J. O'Leary, electrical engineer, of Montreal, has developed a new type of electrical motor, based on the utilization of harmonic vibrations for the source of power. The weight of the rotor is about one-sixth that in an ordinary motor of the same horsepower, and it is stated that a saving of from 20 to 50 per cent. is effected in current used. The invention has been patented in twenty-six different countries, and it is claimed that it can be applied to any machine requiring power for its operation.

Will Extend Plant.—Plans are under way for extensions to the John Inglis Co. plant, Toronto. Wm. Inglis, speaking to a representative of this paper this week, said the biggest part of their business at the present time was repair work, which showed that many firms are in need of new equipment. Mr. Inglis felt that an adjustment of the wage question and a restoration of the public confidence in the matter of steel and other raw materials would go far toward re-establishing business on a firmer basis. His organization is spending $75,000 on improvements for their machine shop, boiler room, foundry and on the plant generally. This, said Mr. Inglis, shows what faith they have in the future. Mr. Inglis said they had been negotiating for some time for the purchase from the city of some land directly across the road from their present site, and that he hoped to be in a position to close this deal and proceed with the building of a new foundry without further delay. Mr. Inglis left the city on Friday on a business trip to Chicago.

An incorporated company to be known as the Prince Edward Island Light, Heat and Power Co. has recently been formed to supply light, heat and power by the use of electricity to all parts of Prince Edward Island, from one large central power station, using coal for generating purposes. It is expected that permanent employment will be provided for about 200 men. Noah A. Timmins, multi-millionaire, and W. J. O'Leary, electrical engineer, both of Montreal, are interested in the company.

E. McG. Quirk, of the Federal Labor Department, is now in Cape Breton district on behalf of the Dominion Government for the purpose of investigating conditions relating to the steel industry. The primary reason for this move is the request of the steel workers for a general inquiry into the situation existing in that section, particularly in connection with the recent wage reductions made by the steel companies.

Engineers' A.B.C. Register

(A Free Service)

POWER HOUSE maintains a Register of qualified engineers which manufacturers may consult and to which we may refer when our advice is requested.

Subscribers are invited to give their name, age, grade, experience, salary and all other information which they think advisable.

Our A.B.C. Register is a free service which engineers and manufacturers do well to avail themselves of.

A—Represents those who seek work or appointment.

B—Represents those who are desirous of bettering their position.

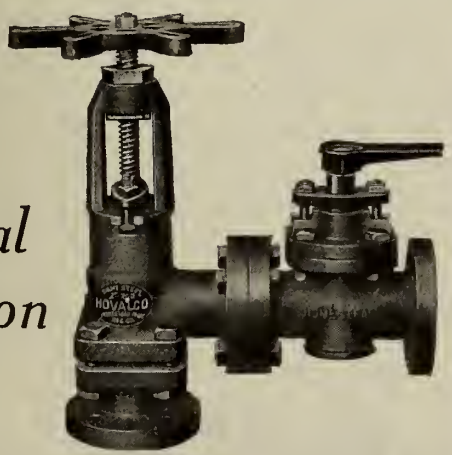
A Safe, Economical Combination



An absolutely reliable combination, consisting of the "Hovalco" Blow-off Valve and the "Homestead" Quarter-Turn Valve.

It puts an end to all blow-off troubles. Nothing can pass when both valves are closed. Gives a clear, straight-way passage when open—no tendency to clog with scale.

Write for full description.

Homestead Valve Mfg. Co.

Homestead, Pa.

Ten hours! More than a day's labor! Think of the cost in dollars!

Such was the result of a test between the flexible type of hack saw and an all-hard blade,

Both were designed to cut the same material! Both were carefully run to deliver the utmost service, but the all-hard blade demonstrated from the start that it cut costs by cutting quicker. On power sawing, where weight is needed to make the teeth of a blade "bite" into the stock, the soft-back saw is not practical. Because of its flexibility, pressure makes it "buckle" Without this weight the cost per cut is too high.

For economical power sawing the proper blade for the particular kind of material to be cut is indicated by the Starrett Hacksaw Chart. It will be mailed to you, free.

A Republic Will Reduce the Size of Your Ash Pile

Ash Pile of Plant Without Co_2 Equipment

Ash Pile of Republic Equipped Plant

A certain well-known plant noticed that with the installation of Republic CO_2 Recorders the quantity of ashes became materially reduced. The logical, and in fact the only deduction was that they were **burning less coal.** And this is Republic Operation "in a nutshell."

Install a Republic and you too will notice the gradual diminishing of your ash pile. You will see your firemen vieing with one another to make their charts "show high" and pointing with pride to records of successful accomplishment. And this represents to you a coal and money-saving that may become even greater by the probable disclosing of unknown wastes in power manufacture.

So simple, accurate and strong is the Republic Equipment that it must appeal to every hard-headed business executive. Consider these features:

No valves, no small tubing and no glass parts to collect gases or sediment and develop trouble.

The pen is adjusted so that the operator can easily see the last record.

The records actually **keep pace** with the furnace.

The entire instrument is complete in an easily-adjustable case weighing only 45 pounds.

NO VALVES
NO GLASS
NO DELICATE PARTS

Republic CO_2 RECORDERS

CONVENIENT SIZE

Worthington equipment for every duty

ENGINEERS, power plant managers, executives in all lines of industry profit by the Worthington policy of building every type in each of its lines of equipment.

Worthington equipment is to be found in every industry, every country that measures machine value by the quality of work done. In power plant service for instance, machinery designed and built by the Worthington Pump and Machinery Corporation has satisfied over 200,000,000 boiler horse power. The period of service extends through eighty-one years—since 1840.

The policy of manufacturing every type of given equipment assures the buyer of impartial advice on his selection and is applied to all lines of Worthington equipment from the small domestic sized water meter to huge oil engines.

Cleaning Your
Stirling Type Boilers CLEAN

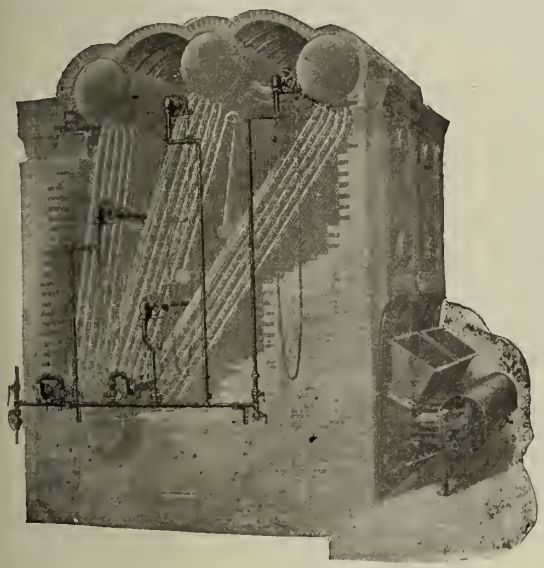

Illustration of the Vulcan Soot Cleaner installed in a boiler of the steep tube type, such as Stirling, Badenhausen, Connelly, and Erie City Vertical.

The Standard boiler usually requires a six-element System; an additional element when a superheater is used; and a five-element System when the boiler is of the low type, and narrow width.

T is important, in considering soot cleaning equipment, to appreciate the cessity for THOROUGH EANING. For without at, the mechanical soot aner is worse than use-ss.

The soot problem in the eep Tube Type boiler cen-es very largely in the first ss. It is vitally essential, erefore, that this pass be oroughly cleaned; although, course, it is almost equally al that the other passes be aned as well.

Vulcan Soot Cleaners have en notably successful in aning boilers of the Steep be, or STIRLING, Type, e principally to the stra-gic locations of their clean-g elements in the first pass. e above illustration shows element located at the top the first tube bank, just below the drum. Another element is located at the bottom, between the first and second tube banks, and is ingeniously protected against the hot gases. Both of these elements have a clean sweep up and down the first bank of tubes—and, because of the Vulcan method of blowing BETWEEN THE TUBES, NEVER AGAINST THEM, the sweep is equally clean straight through each row to the last. The remaining passes are cleaned in the same manner.

If you are considering soot cleaners for your boilers, of whatever type, let us send you our folder "SPENDING $796 TO EARN $1,017.40," giving an interesting financial analysis showing the dividend-paying value of Vulcan Soot Cleaners. Address any of our offices—there is no obligation whatever.

FIRE!

Spontaneous combustion in oily waste is the cause of many fires in Power Plants and Factories.

Eliminate this danger by using Reed's "FIRETITE" Waste Cans throughout your plant. The "FIRETITE" is stoutly built of galvanized steel with high legs and SELF-CLOSING LID. The price is right, too.

Made in three sizes.

We shall be glad to quote you singly or in quantity lots. **Approved by Underwriters' Laboratories, Inc.**

Geo. W. Reed & Co., Limited
MONTREAL

Power Plant Firebricks

Gates Firebricks, when installed in boiler linings, form a solid, compact, non-perishable wall. There are no air leaks. Neither are there clinker-collecting joints.

Gates Firebricks conserve heat. They are especially designed and can be replaced without disturbing the adjoining brickwork. A complete stock of various sizes always on hand. Immediate shipment.

Gates Refractories Limited
382 St. James Street, Montreal

Power Plant Refractory Work

Our wide experience enables us to cope with every problem of Power Plant Refractory Work, Boiler Setting, Furnace Building, Oven Work.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts. It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Write for our catalogue.

Can We Salvage Our Railways?

THIS is the biggest question facing Canadians to-day—overshadowing even the tariff, housing, wages, "buyers' strike," and other vital questions. Why? Because every man in Canada, with a wife and three children, is paying $80 a year, on the average, toward the running of our National Railways, *whether he or the members of his family ever board a train from Jan. 1 to Dec. 31!*

Frank S. Cahill, M.P.—keenest critic in the House of Commons of the Government in railway matters—has written for April 15th MACLEAN'S a striking article, in which he calls for the handing over of the railways to a private corporation—*to run properly.*

Also, in another striking article a prominent, nationally-famous, business man calls for the appointment of a commission of railway experts—probably (so that they may be unbiased) selected in the U.S. After a searching investigation, he advocates that:

1—Certain lines be leased to the C.P.R.;
2—Non-paying lines cut off;
3—Remaining lines handed over, on equitable basis, to private company.

What do business men think of the parliamentary committee appointed to investigate railway conditions? — "Political probe? Pah!—a bunch of amateurs!"

"CANADA'S NATIONAL MAGAZINE"

To Operators of Reciprocating Engines

Through the adoption of superheated steam in steam turbines, engineers are taking advantage of the opportunities of more economical operation and lower maintenance in this type of prime mover.

Even greater economies, however, are open in the thousands of plants where reciprocating engines operate, because these engines actually benefit to a greater degree by superheated steam than do steam turbines.

An idea of the relative economies of superheated steam is disclosed in the following table. By reducing steam consumption, superheated steam saves fuel.

RANGES IN STEAM CONSUMPTION BY PRIME MOVERS.

TYPE ENGINE	Steam Consumption, lb. per hp. hr. Saturated Steam	100 deg. Superheat	200 deg. Superheat
Simple non-condensing	29-45	20-38	18-35
Simple non-condensing automatic	26-40	18-34	16-30
Simple non-condensing Corliss	26-35	18-30	
Compound non-condensing .	19-28	15-25	13-22
Compound condensing	12-22	10-20	9-17
Simple duplex steam pumps	120-200	80-160	
Turbines non-condensing (kw. hr.)	28-60	24-54	21-48
Turbines condensing (kw.hr.)	12-42	10-38	9-34

Elesco Superheaters render greater net returns on the investment than any other single means known or practiced to obtain economy.

Is Your Power House Equipped with a Crane?

The type shown is a double I Beam Hand Overhead Crane, made in sizes from ¼-ton to 20-ton capacity.

We also make Pumps and Vertical Engines.

We can supply you with one which will just suit your needs. The initial expense will soon be dissipated by the saving it will effect.

Let us know the width of your shop, the load to be lifted and the headroom available, and we will submit you an estimate.

A Handbook on the Subject of Scraper Conveyers

OUR new 82-page Catalog has 39 pages of installations showing Jeffrey Standardized Scraper Conveyers in service in various industries, solving all kinds of problems in the handling of loose materials.

The remainder of the book is devoted to Specifications, General Dimensions, and other important data of vital interest to prospective purchasers, architects, engineers, etc.

From this book you can easily select the right type of Scraper Conveyer to meet your requirements, insuring quicker delivery and saving the time and expense heretofore required in making drawings and layouts, special designing of Chains, Pattern Making, etc.

Write TO-DAY for your copy of Catalog No. 257-3

We make Boilers—all Types—Plate Work—Pulp Mill Machinery, etc.

Have Faith in Canada

Canadians are a nation of workers—

We have the cream of the world's natural resources—

We have to-day the largest per capita purchasing power of any nation in the world—

We have to-day the largest per capita savings funds of any country in the world—

Normal efficiency of Canadian labor is being rapidly restored—

Canadian production per farm compares favorably with any other country in the world—

Exhaustion of stocks amongst retailers and wholesalers is everywhere apparent.

Available funds for business enterprises are accumulating in millions.

Will you do your bit to put the needed new life into business?

BUY WHAT YOU NEED—NOW

Sturtevant

REG. U.S. PAT. OFF.

PUTS AIR TO WORK

AIR WASHERS

WILL DISCOUNT YOUR GENERATOR REPAIR BILLS

Decreased profits are often the direct result of increased upkeep costs. Where generators are in service much can be lost or gained according to the attention given to their ventilation. Neglect in this respect means losses of money, time and labor for inevitable and frequent repairs, while the employment of a reliable air washing apparatus will give extra profits, eliminate shutdowns, give greater capacity and longer life to the generators.

Sturtevant (REG. U. S. PAT. OFF.) **AIR WASHERS AND COOLERS**

are a paying investment from the start. They successfully keep the generators free from dust, oily vapors, dirt and ashes, and keep them clean and cool.

With many modern washers the cleansing of the nozzles is a long and expensive job. A full day's labor is required, for each nozzle often has to be taken out and cleaned separately at the work bench. With the Sturtevant nozzle the process is easy. Simply remove the nozzle caps, then turn on the water and let them flush out. Three-quarters of an hour is all the time it takes. Clogging is prevented by the large orifice on the nozzle.

The washer is solidly and rigidly constructed; it is also supplied with a bronze fitted centrifugal pump.

The fact that washers for 250,000 k.w. were sold in one month shows that they are worthy of your consideration. Our catalog 22620 describes their various sizes and advantages. Send for your copy now.

Bailey Fluid Meters Will Tell You Just How Your Steam Is Consumed—

Bailey Fluid Meter
Type C-2

By the use of Bailey Fluid Meters, you can have a continuous check on the steam flow to your turbines, auxiliary power drives, heaters, evaporators, heating kettles, heating systems, drying coils, kiers, vacuum pans, and all other process work. You can be accurately informed at all times of the steam consumption of every unit using either exhaust or live steam.

Bailey Meters are equally dependable for measuring hot or cold water, air, gas or other fluids. Made in types to meet all conditions.

Bulletins upon request.

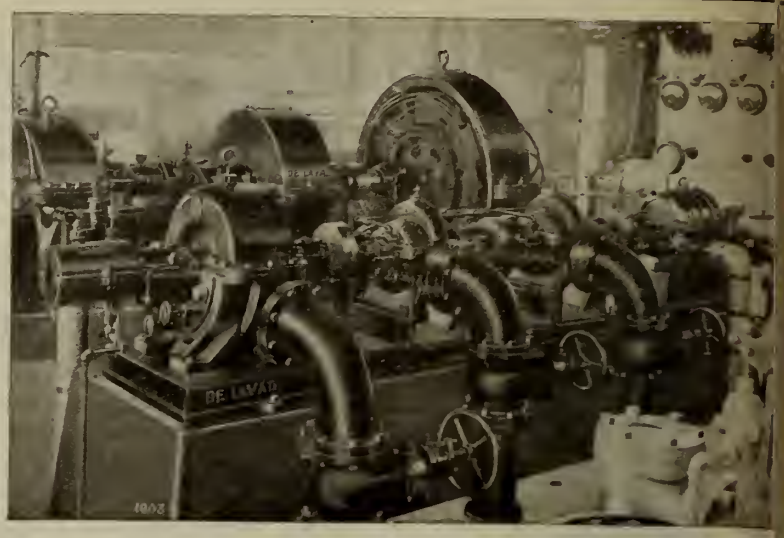
Turbine Drive Throughout Gives Least Trouble and Highest Efficiency

A De Laval turbine power plant costs less to install than a reciprocating plant. Only light foundations and small floor space are required.

De Laval turbine equipment costs least for attendance and supplies. There are no reciprocating and unbalanced parts, no complicated valve gears and few and simple packings. The oiling system is automatic and the exhaust steam is free of oil. There is practically nothing to get out of order.



De Laval velocity-stage Turbine driving De Laval circulating and boiler feed pumps also De Laval Geared Turbine-driven D.C. Generator in background.

By the use of the De Laval Double-helical Speed-reducing Gear, the steam turbine can be applied to driving any kind of machinery, such as rolling mills, paper mills, ships' propellers, large centrifugal pumps and blowers, direct and alternating current generators, etc., etc.

Small pumps, generators, compressors, etc., can be directly connected.

All De Laval machinery is made by precision methods in a modern shop, using the best materials and the highest grade of skilled labor. The limit-gage, interchangeable system of manufacture is used throughout, and parts subject to wear can be replaced immediately with new parts ordered from the factory by number.

State your power plant conditions and literature with advice and suggestions will be submitted by our Engineering Department.

Pressure Gauges

AN excellent example of the merit of Morrison Steam Specialties is the record of a steam pressure gauge, sold to the Grand Trunk Railway 'way back in the eighties. After thirty-two years of constant service, this gauge was returned to us for repairs — one dollar and fifty cents' worth!

MORRISON

"Every installation is a demonstration of merit"

Of course the designs of our pressure gauges and other steam specialties have been greatly improved since this one was purchased. But though their designs have changed their quality has not. The high standard of reliability set over half a century ago by the first Morrison Steam Specialties is fully maintained by the Morrison Specialties of to-day. Their every installation is a demonstration of reliable, efficient, economical service.

THE IDEAL PLANT

An ideal is attained in Elesco-equipped plants because sound engineering has been applied to operating conditions. Guesswork has been avoided. Elesco engineers will study your operation, regardless of the size of your plant, new or old. We will co-operate with you to attain the ideal toward which discriminating engineers are working —the economical, practical and reliable generation of power through the correct application and use of Superheated Steam.

McEWEN HIGH-SPEED AUTOMATIC ENGINES

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country especially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

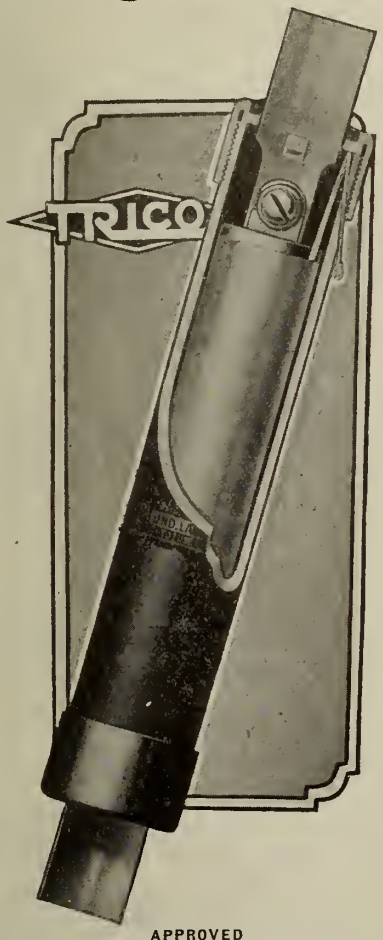
Protect your Plant against Fuse Abuse



APPROVED
Trico Fuses are approved by the Underwriters Laboratories, Inc. Hydro-Electric Power Commission of Ontario, Canada.

TRICO
RED SEAL FUSE PLUG
(Powder-filled)

LIGHT — COMPACT
100% POSITIVE INDICATOR
WRITE FOR SAMPLES

FIRES and accidents that so often result from the "doubling up" of fuse links by thoughtless workmen, never occur in plants where Trico Fuses are installed. For only one Trico element can be inserted in a Trico shell and it is impossible to use a Trico renewal cartridge of a capacity larger than that for which the fuse casing is designed.

Leading power plant engineers have learned that it is the **inside** of a fuse that counts—that's why they endorse the Trico. Let us tell you how this **powder-filled** fuse will not only afford protection against abuse but also reduce the number of blowouts in **your** plant 80 per cent. and save four-fifths of the time men and machines are now idle on account of fuse renewals.

Write us on your business letterhead for complete information. Or better yet, send for a test fuse of the capacity you use most. Put it on your most troublesome circuit and judge by the results.

An exceptional proposition is being offered to distributors and jobbers of electrical supplies in territories where we are not represented.

Trico Fuse Mfg. Co.

Dept. 19, 143 University Ave., Toronto, Canada

New Truths and Old Fallacies

Hardness of Alloys—*Continued*

These figures in preceding article of compression tests show that formulas Nos. 1 and 2—tin base metals—containing respectively 4½ per cent. and 3½ per cent. of copper, were less distorted under compression than formula No. 3, which contained 8 1-3 per cent. copper and also a greater percentage of antimony than Nos. 1 and 2.

Equally strange is it that formula No. 4, containing only 3 per cent. copper and 10 per cent. lead give better results than No. 3. Again all rules were apparently upset by the showing of the lead base formulas, containing no copper, and in some cases no tin.

But this carries out, to some extent, the statement made by Charpy, that the eutectic is the limit of the strength of an alloy.

Antimony has the most pronounced effect in hardening an alloy, but at around 18 per cent. antimony and beyond the alloy becomes very brittle, thereby losing any value of malleability. For this reason the antimony content of alloys is kept within certain bounds and tin is added to give additional hardness, without impairing malleability and in this way the equilibrium of an alloy is maintained.

If tin in a lead base alloy has any other advantage, we do not know it, and its use beyond a comparatively small percentage lowers the fusibility.

If copper is also added to a lead base metal it still further increases fusibility and also comes to the surface in the form of "creepers," makes the mixture dirty looking and sluggish in pouring and when heated cupreous gases sometimes form and produce blow holes.

(Continued next month).

SIMPLICITY

The Stowe Stoker not only has a small number of *total* parts, but a very small number of *moving* parts. There is a complete absence of manually-operated adjustments for controlling the air-distribution.

The Stowe Stoker is really simpler than the chain grate. Alternating tuyeres and chains—that's all there's to it. Drippage falls into a pit provided for that purpose, instead of clogging air passages. There are no air ducts in the firing aisle.

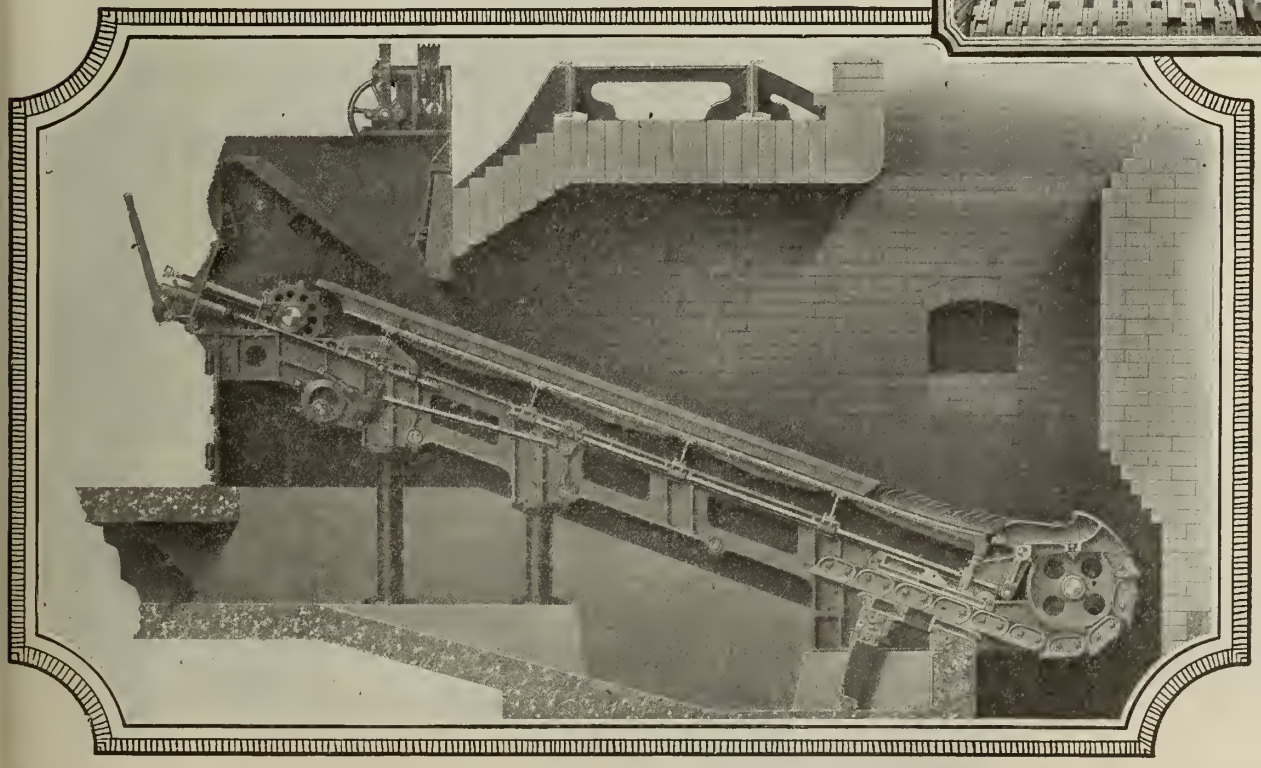
As compared to the chain grate, only *half* the grate surface of the Stowe Stoker actuates; and yet, it provides a graduated air supply for the various stages of combustion, and adapts itself to force draft with no more ado than is involved in the application of forced draft to a hand-fired grate. Furthermore, it positively discharges the refuse at a rate which can be controlled independently of the rate of feeding.

When one considers first, the many striking features and advantages of the Stowe Stoker, and then, the marked simplicity of this mechanism, the realization comes that here is a truly great *achievement* in mechanical equipment design.

THE STOWE STOKER

EMPLOYING MECHANICAL DRAFT

Its fundamental principle is a conveyor feed, positive in action from coal-hopper to ash-pit.



Branch Offices: 1366 Peoples Gas Bldg., Chicago—504, 50 East 42nd St., New York—901 Oliver Bldg., Pittsburgh

Consider the Lining

The finest furnace in the world is an economical failure unless its lining is built to withstand fire's fury.

PLIBRICO
JOINTLESS
FURNACE LINING

will withstand temperatures up to 3100° F. It is a plastic refractory, pounded into shape with a mallet and smoothed with a trowel. Being jointless, no clinkers can adhere, and there is no mortar to fall out, therefore disintegration cannot start.

No costly repairs, no shutdowns, for the furnace lined with PLIBRICO.

Sold in steel containers of distinctive appearance as shown below. Supplies for immediate delivery at Montreal, Toronto, Winnipeg, Vancouver and Calgary.

Ask for book L13 on Furnace Building.

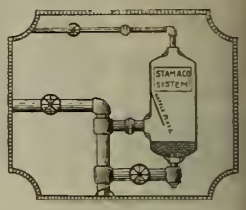
THE STAMACO SYSTEM



Blow-down of boilers is considered a big loss.

Stamaco eliminates blowing down, thereby creates a saving.

Do you realize that every time your engineer blows down your boiler, that 8% to 12% of fuel is wasted.

Stamaco is guaranteed to save fuel and labor and keep your boiler automatically and continuously clean.

Further details on application.

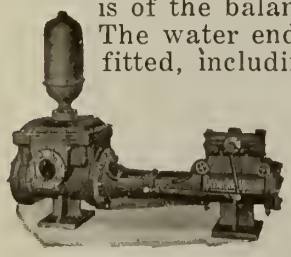
AMERICAN-MARSH PUMPS

SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.

The line also includes—
Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

GARLOCK PACKINGS

BETWEEN THE COAL PILE AND THE ENGINE

At this time more than any time in the history of engineering, highest efficiency is demanded. A blown out gasket can shut down a plant just as surely as a broken piston rod. Every leaking manhole joint or pipe flange represents a distinct loss, and it has been demonstrated by scientific experiment that there is no limit to the loss caused by undue friction on piston rod and valve stem packed with an inferior packing, and the constant use of a wrench in attempting to stop leaks at rod glands. Let Garlock No. 950 Gasket, cut from No. 900 Sheet Packing, reduce the loss between coal pile and engine.

THE GARLOCK PACKING CO.
HAMILTON, ONT.

SPARE THE ROD

Building a one-piece furnace lining without special or tools—No separate brick and no clay mortar joints.

While Business is Slow

Install New Boiler Furnace Linings and Baffles

Now, is the ideal time to re-line your boiler furnace, or put in new sloping baffles. Then you will avoid annoying delays and loss of time later on.

Permanent One-piece Linings and Baffles of

BETSON'S PLASTIC FIRE BRICK

are easily installed without special forms or tools, even with inexperienced help.

The high temperatures reached by modern boiler furnaces, cause rapid disintegration of clay mortar joints, followed by complete destruction of the fire brick linings, arches, etc.

A solid one-piece lining, including front and back arches, side walls and baffles, costs but little to install in any make or type of boiler, and saves fuel, annoying shut-downs, costly repairs, and increases the amount of usable power from the fuel you pay for.

Complete details of the uses, methods of installing, how to order, measurement blanks, etc., are contained in a booklet of information which we will gladly send you. Tell us the individual to whom it should be addressed.

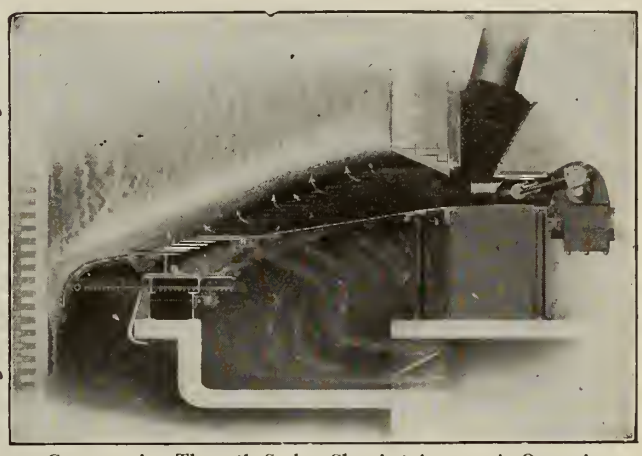
BURN ALL GRADES OF COAL



Cross-section Through Stoker Showing Automatic Operation

No device has shown itself better adapted to burn any available coal than

RILEY UNDERFEED STOKERS

Low-grade coals—those high in ash—in sulphur and clinker-forming qualities—can be handled successfully for the following reasons:

1. The moving grates keep the clinkers broken up—combustion is intensified—the fuel bed is always active, even and in a homogeneous state.

2. The rocker dump, with its combination of vertical thrust and rocking motion, grinds up—discharges the ash continuously and automatically—keeps the fire clean and the bridge wall free from accumulations.

3. The underfeed feature makes possible high capacity and instant response to overload demands.

Our engineers will be glad to acquaint you with the wide range of fuels now being handled by the RILEY UNDERFEED STOKER under many varying conditions.

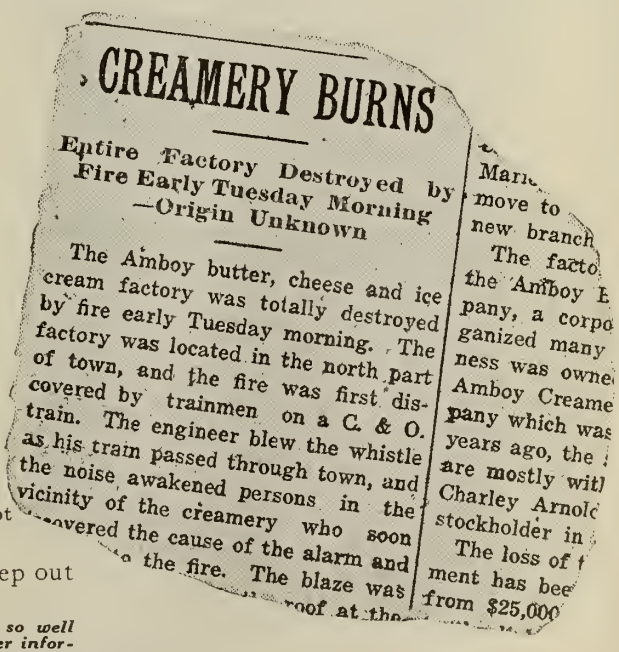
A Test We Didn't Make

Maybe you are one of those who are a little skeptical about manufacturers' tests on insulating material. All right—here is one there can be no question about. Not even the customer made it. It was made for him, and the making of it destroyed his whole plant except the hardening room. But read this letter from the Amboy (Ind.) Creamery Company, dated January 12, 1921:

> "On the morning of December 21 our entire plant was consumed by fire. Our refrigerating room was inside of the creamery. After the fire the ante room was all burned down, and the hardening room, which was built of two layers of three-inch corkboard, went through the fire without being burned very badly. The outside of the room, which was covered with lumber, was all burnt off and just the cork was left.
>
> "Ten hours after the fire, when we opened the door, the temperature of the room was 10 degrees below freezing. We expected to find the room very hot and that the ice cream would be ruined. The 150 gallons of ice cream was in fine condition; could not tell it had been through a fire.

"We feel that the cork must have been all you said it was or it would not have stood the test it did."

A very satisfying test. Nonpareil Corkboard certainly does keep out the heat.



CREAMERY BURNS

Entire Factory Destroyed by Fire Early Tuesday Morning —Origin Unknown

The Amboy butter, cheese and ice cream factory was totally destroyed by fire early Tuesday morning. The factory was located in the north part of town, and the fire was first discovered by trainmen on a C. & O. train. The engineer blew the whistle as his train passed through town, and the noise awakened persons in the vicinity of the creamery who soon discovered the cause of the alarm and gave the fire. The blaze was

Would you know why your steam suddenly dropped ?

A fireman leaves a fire door open while he reads the sporting events of the day. Consequently your steam pressure takes a decided drop. Would you be able to locate the cause? Bailey Boiler Meters would enable you to.

The chart records of Bailey Boiler Meters show to the engineer the performance and condition of each boiler. He can tell the presence of leaking tubes, broken-down baffles, dirty tubes, defective settings, improper feeding, or negligence of any sort on the part of the firemen. The charts are a positively dependable record of the boiler room results obtained each day.

Let us help you get the most from your coal. Write to-day for a copy of our bulletin.

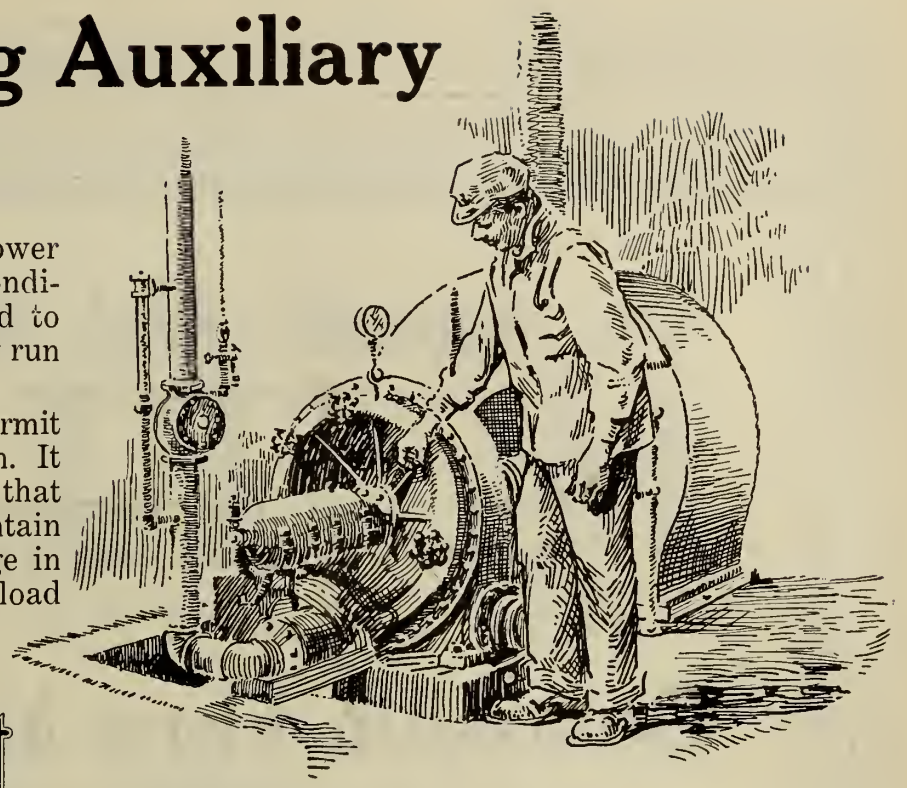
Steam Saving Auxiliary Drives

The auxiliaries in the modern power plant seldom operate under ideal conditions. Most of them are subjected to severe load fluctuations and usually run underloaded.

The high price of coal does not permit extravagance in steam consumption. It is therefore extremely important that the drives selected are able to maintain a good economy over a wide range in load. Operate at nearly full load economy at one-quarter and one-half load.



Sturtevant (TRADE MARK)

Steam Turbines

They are not controlled by throttling down the steam, but by shutting off one or more of the several steam nozzles by the hand wheels on the turbine casing. The nozzles remaining in service undergo no change in efficiency.

The turbines are scientifically designed and all parts are constructed accurately to gauge of the best obtainable materials.

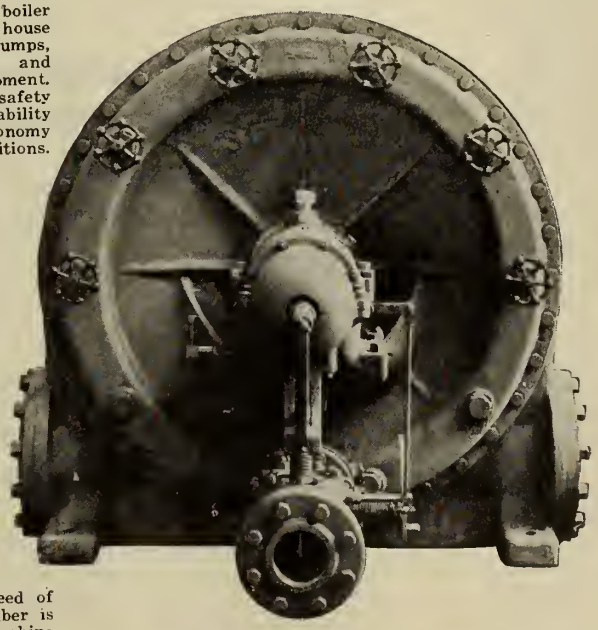
The assembly is made under expert supervision and a true running balance is established.

A positively dependable shaft governor holds the speed regulation within close limits and entirely adapts these turbines to drive electric generators.

Consultation with our engineers is recommended before selecting any turbine drive.

Write for Bulletin.

Sturtevant Steam Turbines are used to drive exciters, boiler feed pumps, house pumps, fire pumps, fans, blowers and special equipment. They combine safety and dependability with high economy under all conditions.



When the speed of the driven member is below the turbine speed Sturtevant Transmission Gears are used to obtain maximum efficiency.

Heating The New Parliament Building

A Central Plant Has Been Installed Which Heats Nine Buildings —The Main Steam Pipe Runs Nearly a Mile From the Central Station—Forced Circulation and Indirect Heating

By T. H. FENNER

WHEN the citizens of Ottawa first heard that their post office was to be heated during the winter by a heating plant situated nearly one mile away, and that this same plant would also heat the new Parliament Buildings, and several others, there were not lacking those who said it could not be done. Dismal prophecies of failure and money wasted were freely indulged in, but to-day the plant is a complete success, and has saved money instead of wasting it.

The consulting engineer for the plant, M. F. Thomas, of Toronto, and the contractors, W. G. Edge, Ltd., of Ottawa, are both to be congratulated on the successful carrying out of the scheme, which is a big one. In fact, one cannot help but pay an involuntary tribute to the broad vision of the engineer who conceived the idea and carried out the arrangement with all the infinite details necessary to its successful completion. It is one of the biggest, or possibly the biggest, central heating scheme on the continent of America, and as it stands at present is only half the size it will eventually be, when the additions provided for are made.

Heats Nine Buildings

The power house is situated on the banks of the Ottawa River, at the foot of the cliff, round the top of which winds the famous "Lover's Walk." The cliff was cut away at this spot to admit the building of the power house, and this can be seen in the illustration of the outside of the plant. The buildings supplied with heat are nine in number, and starting from the plant and going east they are as follows: Department of Soldiers' Civil Re-Establishment, Supreme Courts, West Block of Parliament Buildings, the new Parliament Buildings, the old library which was left standing after the fire, the East Block of the Parliament Buildings, the Longtin Block on Wellington Street, and the Ottawa Post Office. Some idea of the heat supplied may be gathered from the fact that there are between 13,000,000 and 14,000,000 cubic feet in these buildings. The new building is arranged so that the air can be changed four times every hour.

The length of the tunnel from the boiler room to the post office is practically one mile, and it contains the main steam pipe, the summer heating line, the hot water circulating pipes, two in number, the steam condensation return, and the air line. These pipes are all arranged on the side of the tunnel, and a clear space left for walking and effecting repairs. The tunnel is about 8 feet high, well lighted and dry.

The Heating Plant

The entrance to the plant is from the top, which is on the street level and about 85 feet above the river bank on which it stands. The ground in front of the power plant as shown in the illustration is mostly reclaimed. The front

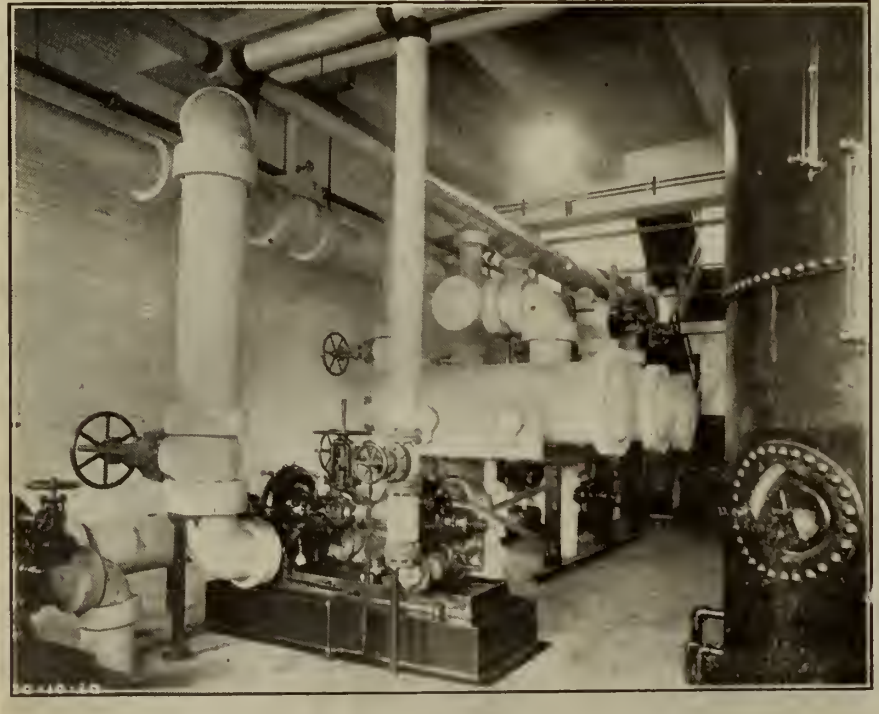
THE POWER HOUSE. THE TOP OF THE BUILDING IS AT STREET LEVEL.

wall of the building can be seen running in behind the cliff, which was blasted out to make room for it. At the other end can be seen the wall left rough to accommodate the new addition when it becomes necessary. The four square openings right in the bottom of the wall are in communication with the ash pits and supply air for the fires. They are arranged with dampers, so that the supply can be regulated in very cold weather, and according to the number of boilers in use. The top of the stack is 175 feet above the top of the boilers, and natural draught is used. On the top of the building a coal weighing scale has been provided, but this has not been in use as yet. The four windows above the square openings are in the boiler room, and the blank wall above them is the outer wall of the concrete coal bunker, which has a capacity of 1,800 tons. This is filled from the top, and at present the coal is all drawn by teams, but eventually a railway siding will be run in so that the gondola cars can unload direct in the bunker. It is quite probable that when the full plant is installed provision may be made for receiving coal by water and elevating it up to the bunker.

One enters the power house by means of a small house erected alongside the scale house, and first of all pass down three flights of iron stairs till the chief engineer's office is reached. As can be seen this is a large square space, containing the instrument board and a comfortable desk. On the other side of the partition behind the instrument board are the toilets and shower baths for the plant staff. There is ample room on this landing for the installation of a lighting plant if this should ever be considered. In fact, all through the power plant there is ample space. The means of entrance, and the continual descending of ladders after one gets in the plant, are strongly reminiscent of sea-going days, and we do not recall any plant that is quite so much up and down as this. However, it makes an excellent arrangement, and an elevator is installed to take passengers and freight from the lower floor to the street level. The boiler room can be reached by team or truck by a roadway running round the end of the power house on to the river bank, so there is no difficulty in getting supplies or spare parts to and from the plant.

ANOTHER VIEW OF HEATERS

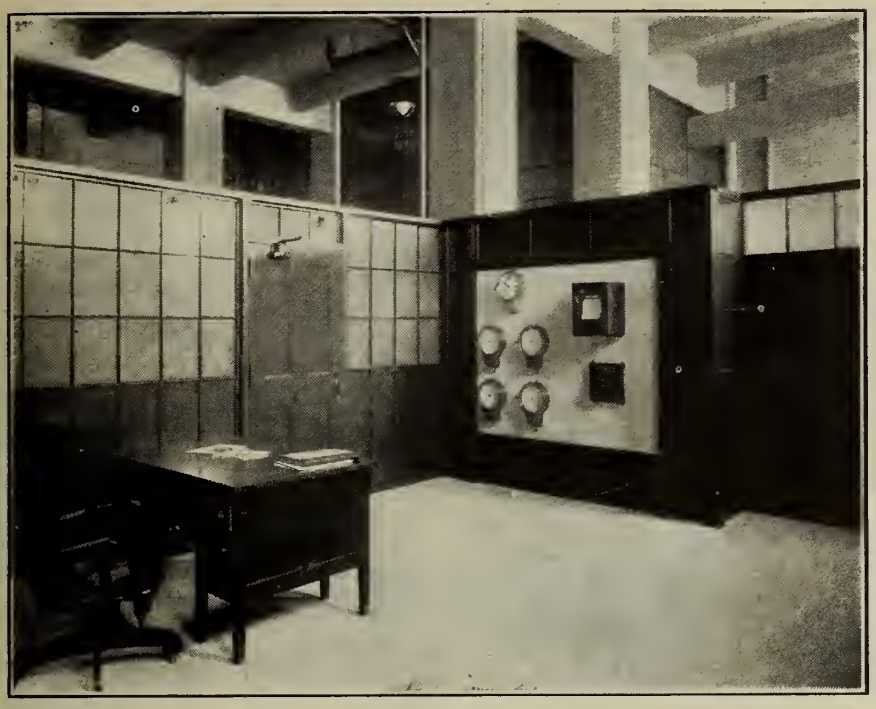
In the chief engineer's office we met the engineer in charge, W. McIninch, who took no end of trouble in showing us around and imparting all the information we could wish for. He has been on the job practically since its inception, and is thoroughly au fait with everything in connection with it. Incidentally, he takes great pride in its successful operation, and chuckles with satisfaction as he tells about those who prophesied its utter failure. With Mr. McIninch in the lead we descended some more ladders and started our trip from the proper place, that is the firing floor of the boiler room.



FORCED CIRCULATION HEATERS, PUMPS, AND EXPANSION TANK.

The Boiler Plant

The boiler plant consists of four Goldie & McCulloch water tube boilers of 500 horsepower each. They are fitted with Murphy stokers, and the grate surface is 92 square feet per boiler, a total at present of 368 square feet. The coal is fed from the overhead bunker into a travelling hopper, which automatically weighs it, a Fairbanks scale on the floor level punching a ticket, which is kept as a record of coal burnt. In the illustration the chute can be seen filling the hopper of number one boiler, and the scale suspended from the chute can be seen directly in front of the boiler. The ashes are carried along a duct under the floor by a Link Belt Co. drag conveyor, and at the far end of the building are delivered to a bucket elevator, which delivers them into an overhead bunker, from which they are dumped into the carts. Eventually, of course, there will be a siding here and the ashes will be loaded on to the railway cars direct. Each boiler is fitted with an 8-inch steam pipe, discharging into a 12-inch main header, which delivers the steam to the



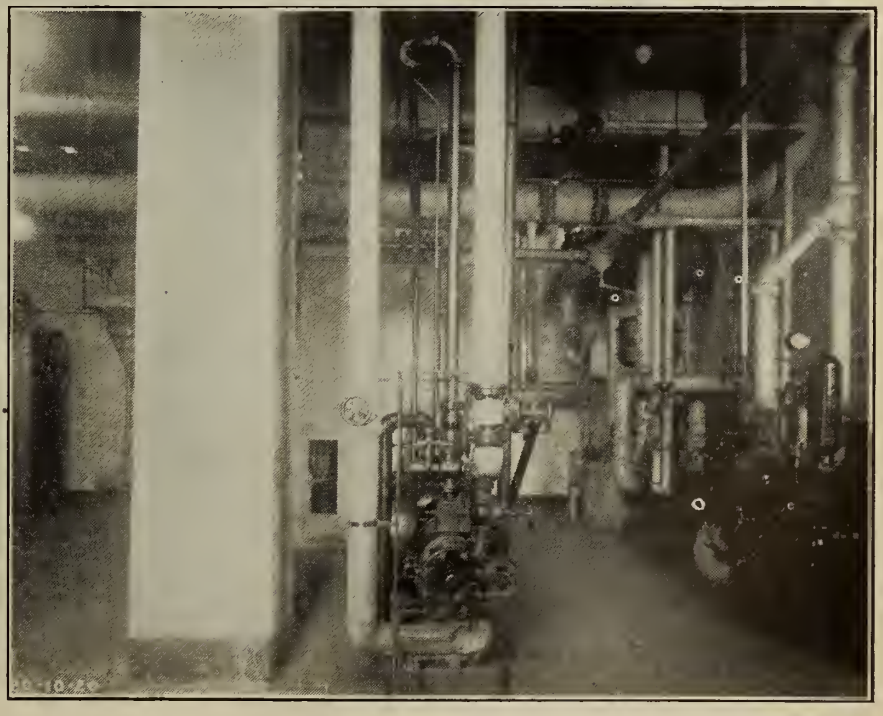
THE OFFICE AND INSTRUMENT BOARD.

buildings. This header is carried on rollers on top of the boilers, and the connections to each boiler are made through a U-bend to allow for expansion. The header itself is connected to the main pipe going through the building by a similar bend, and ample provision is thus made for expansion in both directions. Each boiler is fitted with an Ellison draught gauge, and the breeching between combustion chamber and stack of each boiler is fitted with a thermo couple, which is connected to a five-point recording pyrometer in the chief engineer's office, so that a record can be kept of the stack temperature of any boiler over any period wished. This recording pyrometer can be seen on the right of the instrument board in the illustration of the office, while just below it is the five-point switch. There is a CO_2 recorder of the Simmance Abbadie precision type fitted for all boilers. The feed header from the main feed pumps is carried along the top of the boiler, 4 inches diameter, and is reduced to 2 inches at each boiler, while the pipe leading to the second drum is reduced again to 1½ inches diameter.

The feed water is supplied to the boilers through a Webster heater and delivered to the boiler by outside packed pumps made by the Bawden Machine Co., Toronto, 16 x 9 x 20 inches. One of these pumps can be seen in the right hand corner of the illustration showing the pump room, which is on the ground floor, just alongside the boiler room. Between the feed pumps and the heater are installed the vacuum pumps, 10 x 14 x 20, which handle the returns from the steam lines and maintain a vacuum of 10 inches on the return line. These pumps were also furnished by the Bawden Machine Co. It is very creditable to the workmanship on the return pipe lines that a vacuum of 10 inches can be maintained through all the thousands of feet of pipe that go to make up the return lines throughout the buildings. On the left, close to the column, can be seen the steam-driven air compressor, while in front of that machine there is another of the same size motor driven. The compressors are Ingersoll Rand 9 x 8 and the electrically driven machine is belt-driven from a 25 horsepower 220 v. Westinghouse 2-phase induction motor. These compressors supply air at 110 pounds pressure to the buildings, and this is reduced down to the required amount for operating the thermostatic valves, elevator doors, etc., in the various departments. The main steam pipe can be seen coming down in a bend from the boiler room, and extending across the pump room ceiling. It goes up on the other side of the pump room to the floors above and the tunnel entrance. The steel ladder leading up to the upper floors can be seen just behind the square column, with the air receiving tank just to the left of the stairs.

The Forced Circulation System

The new building of the Parliament Buildings is supplied with direct hot water radiation, the water being circulated from the power house. The Commons chamber, Senate chamber and corridors are supplied with indirect heating by means of fans. The forced circulation system is installed on the third floor of the power house, that is the floor just below the street level, and a little below the entrance to the tunnel. There are three Ross heaters installed, which are furnished with exhaust steam from the pumps on the lower floor, but during the past winter one of these has been found quite sufficient to supply the new building. About 50,000 gallons of water are in circulation, and this water is circulated by a Terry turbine driving a centrifugal pump. The heaters are arranged so that they can be supplied by steam through a reducing valve in case of there not being sufficient exhaust steam to supply the necessary heat. The water in the system is under an air cushion of 90 pounds per square inch, which is supplied to the expansion tank which can be seen in the right of the illustration. A Venturi meter is installed, which is shown in the other view of the heater room, which records the



AIR COMPRESSORS, FEED HEATER, FEED PUMPS ON LOWER FLOOR.

THE BOILER ROOM.

amount of water flowing through the system at any time, as well as keeping a permanent record. The recording thermometer on the left of the board is provided with a double pen, which records the temperature of the water returning from the building. It is a remarkable fact that in the most severe weather experienced so far the difference in these temperatures has never exceeded 14 degrees. There is another recording thermometer connected to the outside air. The mains carrying the hot water to the building are 12 inches diameter. The entrance to the tunnel is in the left hand corner of the heater room and cannot be seen in either of the views here shown.

The Tunnel

From the level of the heater room one mounts a short flight of the iron ladder and then steps directly into the tunnel, which stretches away into what seems a limitless distance. The tunnel follows the course of Victoria Street, the roof of the tunnel being about four feet under the street level, and gradually mounts up towards the eminence on which stands the Parliament Buildings. It then goes under the famous Lover's Walk, and then jumps up a stage into the basement of the new building. Our illustration shows the corner where the lift is made, the iron ladder at the side being the means of getting from tunnel to basement. Before one reaches here there have been several taps off the main pipe, to supply the various buildings before enumerated, and there are some good examples of pipe bends. We have illustrated one of these, showing the main steam pipe and the two hot water pipes turning from the tunnel into the main building. On the various lines there are a large number of expansion joints, and these are all of the sleeve type, made by the Ross Heater & Manufacturing Co., New York. There are 15 of these joints on the steam line and 24 on the hot water line, with five on the return line.

The Air Washing Plant

The indirect heating plant for the Commons chamber, Senate chamber and corridors is in the basement of the new building, and is supplied with steam from the main steam line from the power plant. The fan installation consists of 17 "Vento" fans, seven of which are on the air supply and ten on the exhaust side. The total heating surface of the Vento heaters is 10,341 square feet and the capacity of the seven supply fans is as follows: 35,000, 20,000, 15,000, 25,000, 20,000, 15,000 and 15,000 cubic feet per minute, the total capacity being 145,000 cubic feet per minute. The air is supplied after passing through air washers supplied by the Canadian Blower and Forge Co., Kitchener, and there are seven of these washers. The air is first drawn over a preheating coil and then passed through a spray of water, after which it passes over another coil which dries

SOME PIPE BENDS.

PIPE RISING FROM TUNNEL TO BASEMENT ON NEW BUILDING.

Future Plans

The plant will be probably doubled in the near future, as the Government are contemplating erecting a number of new office buildings for departmental purposes, all of which will be supplied from the central heating plant. There is ample room to increase the boiler room installation by the addition of four more boilers, and it is proposed that when this is done, and the new stack built to care for them, the two stacks will be enclosed in an ornamental stone tower. This would undoubtedly give the whole structure a very pleasing appearance when viewed from the outside. In the pump room there is plenty of room for addition, and judging from the performance of the plant so far there is ample heater installation to care for everything for some time to come.

A Saving Here

While no attempt has been made as yet to obtain economical test data, pending the completion of the job in all particulars, some idea of the benefit obtained from the plant can be given. For instance, the building which was burnt down had its own heating plant, which consumed 25 tons a day. The east and west blocks burnt about that between them. The present plant has supplied these buildings and six others with ample heat on a consumption of 45 tons per day. This is a remarkable result, and amply justifies the undertaking. In all of those miles of piping we did not come across a leak, and we walked from end to end of the tunnel. A patrol is kept up of one man every shift making a complete tour of the installation and reporting on any defect he comes across. The firemen and watch engineers work in three shifts of eight hours

(Continued on page 29)

and heats it. The washers are constructed of bronze and aluminum to resist corrosion. The steam coils are all under thermostatic control. The thermostats are set to a certain predetermined temperature, and when this is reached the thermostat opens the air supply which closes the steam valves. The same arrangement is used for operating the various dampers on the air ducts and by these means a very close temperature regulation is obtained. The fans and washers are installed at each end of the building and the air is carried to the various rooms through galvanized iron ducts. The direct radiation provided in the new building is in all 44,341 square feet.

The illustration taken in the basement of the new building shows the pumps for supplying the air washers in the foreground. These are motor driven. On the left is shown the casing of one of the air washers, one of the fans being seen on the right. The air duct can be seen above, as well as some of the piping. Where this photograph is taken is probably half-way from the power plant to the extreme end of the line.

A Course of Instruction for the Graded Certificate

The Subject of Valve Setting Is Taken Up—Placing the Engine on Centre — Setting the Eccentric — Setting the Slide Valve— Setting the Corliss Valve — Direct and Indirect Motion

By T. H. FENNER

IN considering the subject of valve setting we will take up first the case of a plain slide valve and assume that the eccentric is loose on the shaft. It becomes necessary then to first secure the eccentric in approximately its correct position, and also to have the valve on the spindle at as near as possible the correct distance from the end of the spindle. We are assuming, of course, that there are no drawings and no data to guide the engineer. This is often the case when an engine that has been out of use for some time may be again put into service, or perhaps a second-hand engine has been bought and shipped knocked down, or it may be a new engine which the operating engineer has to erect himself.

In most stationary engines the eccentric is secured to the shaft by set-screws only. If it is keyed on, of course, there will be no trouble in finding its correct position, but the set-screw is the usual method of fastening. In order to get the valve at approximately its correct position turn the eccentric round on the shaft until it is at its extreme position on the inward side of the shaft, and measure the amount the steam port is open. Then turn the eccentric round to its extreme position on the outside of the shaft, and measure the port opening at the other end. These should be about equal, and if they are not, move the valve on the spindle until they are. The valve is now close enough to its position to allow the eccentric to be set. In order to do this the engine should be set on the centre at either end.

The method of setting an engine on the dead centre has been described so often that we feel like offering an apology for doing it again. There are, however, always a certain number of men who have not had the job to do and who have not read about it, so it will be described briefly here.

Placing the Engine on Centre

Turn the engine over until the piston is nearly at the end of its stroke at whichever centre you are going to mark first. When the crosshead is about two to three inches from the end make a mark on the guide shoe and a corresponding one on the crosshead. Then take a piece of round iron or steel pointed at one end and turned into a right angle at the other end, which is also pointed. Make a centre dab on the frame of the engine and place the straight end of the trammell or round iron in this centre dab, while with the other end a mark is described on the crank web or flywheel, whichever is most convenient. Now turn the engine over the centre until the mark on the crosshead and guide correspond again, and scrive another mark with trammell on the crank or flywheel. If the space between these two marks is divided, and a mark made between them, and centre dabbed, the turned point of the trammell will just fit into this mark when the engine is on the dead centre. One might think that a mark placed on crosshead guide at the end of the stroke would be sufficiently near, but this is not so, as there is always a certain amount of wear taking place, which would cause false indications to be given by a mark of this kind. Once the mark is made by the trammell it is correct for all time, as long as the trammell itself is not bent or abused. The accompanying illustration shows the method clearly.

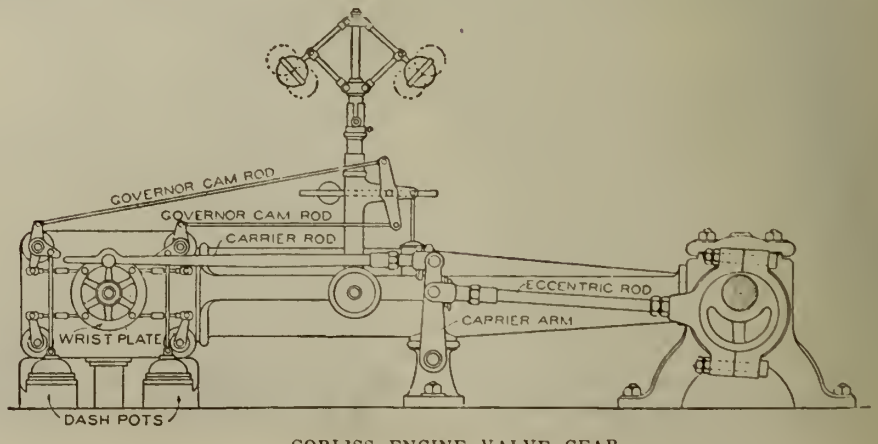
Setting the Eccentric

Having placed our engine on the centre, the next step is to turn the eccentric round on the shaft until the valve is just open to steam at the same end that the piston is at. That is, the valve is admitting steam to the piston to move it on its stroke. Secure the eccentric temporarily at this position and turn the engine round on to the other centre, finding the centre in the same way as the first one was found. The valve should be open practically the same amount on this end as it was at the other. Let us go into a little more detail.

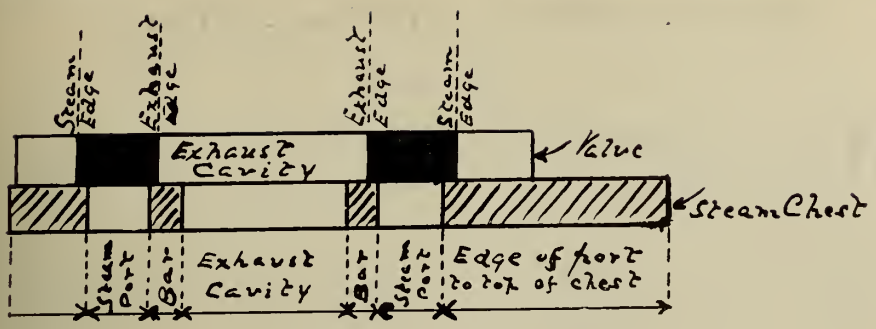
Suppose we set the engine on the head centre first, and set the eccentric so that the valve is open to steam 1-16th inch when the crank is on the dead centre. We now turn the engine around to the crank centre and find the valve is open to steam 3-16th of an inch. Now if the valve is moved down on the spindle 1-16th the lead will be equal each end. We want to have a little more lead at the crank end on account of the effect of the connecting rod, which we have explained before, but if we have 3-16th at one end and only 1-16th at the other it is rather a lot. We want to get a little more lead on the head end than 1-16th, and still have a chance to give the crank end a little more lead than the head end. The only thing to do is to advance the eccentric on the shaft. Turning back to the head end centre, move the eccentric till we have the valve open to steam 1-8th inch, and then move the engine over to the crank end again. We shall now find that we have increased the lead on the crank end to 5-16ths. That is a difference of 3-16ths between the head and crank end. Now if we move the valve on the spindle towards the crank end one-sixteenth, we shall have 3-16ths at the head end and ¼ inch at the crank end, which should be about right. These amounts would vary, of course, with the size of the engine, but the idea is just the same.

Now while the cover is off it is a very easy matter to check up the cut off points at each end of the cylinder by slowly turning the engine round and noting the position of the crosshead when the edge of the valve just covers the steam port on head and crank end. The exact moment when released can also be determined by the use of staffs which will be explained and thus every position of the valve may be known at the time it is set. Generally speaking, if the leads are right at each end the other positions will take care of themselves.

We have seen that in setting the valve described above we have adjusted both the position of the valve on



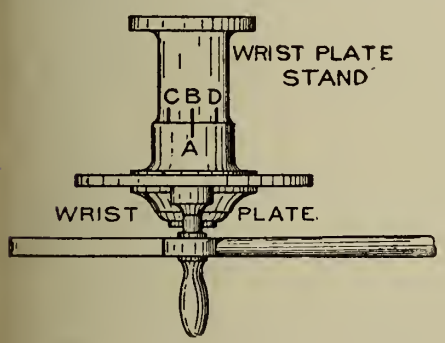
CORLISS ENGINE VALVE GEAR.



STAFFS FOR SETTING VALVES.

the spindle and the position of the eccentric on the shaft, and from what we have said in previous lessons the student should be able to deduce some useful rules.

The first thing that will occur to the thoughtful reader is that by altering the position of the eccentric every function of the valve is altered. We have shown this before in speaking of valve diagrams, but it has been our experience that this fact seems hard to grasp by many young engineers. It is simply this: When the eccentric is placed further ahead of the crank and the crank is at dead centre, then, of course, the eccentric is that much more ahead of the crank all the way round. Then the rod and valve which are operated by the eccentric will be at the end of their



MARKS ON WRIST PLATE AND PIN.

stroke and have started to return when the crank has moved through but a small angle and thus will cut off the steam from the piston at a much earlier portion of the stroke. At the same time the exhaust edge of the port will be opened sooner, thus making release earlier, and the extreme end of the stroke being reached the valve starts its return journey, making compression earlier, and also opening to steam long before the piston reaches the end of its stroke. If the eccentric is set too far back the opposite results occur and every operation is late. Therefore, when setting a valve, if you find that lead is late at each end and cut-off is late at each end, then the eccentric must be moved ahead on the shaft. If the lead at each end is too great and cut-off is taking place too soon, then the eccentric must be moved back.

This same method of setting applies to the double ported valve, and the piston valve. With a piston valve it is, of course, very hard and in some cases impossible to see the amount of lead when the steam is taken on the inside, and in this case the method of using staffs is resorted to. This consists of making a staff on which is marked off the position of the ports in the valve chest or the liners, and a second staff which is made to conform to the bars on the valve. The valve is set by measuring the distance of the valve from the end of the casing and then laying the staff which represents the valve on the staff which represents the casing at exactly the same distance. The position of the ports can then be plainly seen and the adjustments made accordingly.

We have seen above the method of placing the eccentric in position and getting the valve in its position on the spindle when the eccentric is loose on the shaft. After making these adjustments it is necessary to take an indicator diagram to make the final adjustments, and these we shall deal with in due course. Before coming to that we will take up the setting of Corliss valves and other types of drop gear valves.

Setting the Corliss Valve

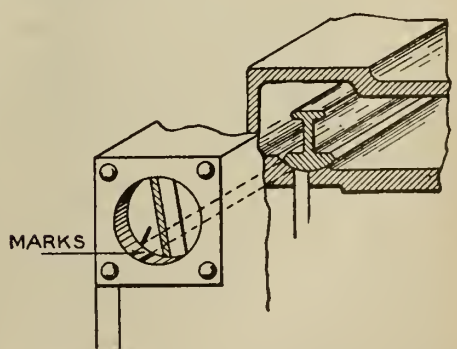
Corliss valves are operated either by one eccentric and a wrist plate, to which the reach rods of all four valves are connected, or by two eccentrics, one of which operates the steam valves and the other operates the exhaust valves.

The first thing to adjust on a Corliss gear is the reach rod, which operates the wrist plate. This rod is usually operated from a lever placed on the engine frame, which is operated by the eccentric rod direct. The eccentric rod length is fixed, but the reach rod is made adjustable, usually by a right and left-hand thread in its length, which makes it possible to either lengthen or shorten it. The wrist plate is usually marked by the makers with a chisel mark, and this mark corresponds with marks on the wrist pin. There are usually three of these, one in the centre and one each side of the centre. These two outside marks show the limit of travel of the wrist plate. The eccentric being left loose on the shaft is turned through one revolution, and the marks on the wrist plate and pin carefully watched. The mark on the wrist plate should travel from one outside mark on the pin to the other, but no further. If the wrist plate travels too far towards the head end the reach rod must be shortened, while if it goes too far to the crank end it should be lengthened. This is fairly obvious. This is the first part of the adjusting and must be correct before anything further is attempted.

The next step is to move the covers from the back side of the valve chambers, that is the side away from the gear. When the cover is removed there will be seen marks on the end of the chamber corresponding with the port opening and marks on the valve end which correspond with the face of the valve. The end of the valve is circular, but the part that does the work is of T shape, the stroke of the T being a part of a circle of the same radius as the bore of the valve chamber. Now turn the eccentric round on the shaft till the centre mark of the wrist pin is in line with the mark on the wrist plate. The valves will then be in approximately mid position. In this position the steam valves should be overlapping the steam ports by about one-quarter to seven-sixteenths of an inch, according to the size of the engine. The exhaust valves will be also in their mid position, that is, just about to open. The exhaust valve on one end will, of course, be closed when the steam valve is open.

The steam rods, or reach rods, connecting wrist plate and steam arm, and the exhaust valve reach rods connecting the exhaust valves to the wrist plate, must now be adjusted by their right and left hand screws until the valves are in correct position, as nearly as possible. After this is done, turn the engine over to the dead centre at either end.

The governor must now be raised on to its stop, so that the steam hooks will engage. Now turn the eccentric round on the shaft until the valve at the end where the piston is just opens to steam by the amount of lead required, say 8 inch. Then secure the eccentric on the shaft, as this will be its angle of advance, approximately. Now turn the engine over to the other centre, and the valve at that end should also show the amount of lead required. If not, adjust the rod to give the required lead.



MARKS ON END OF CORLISS VALVE.

The governor reach rods should now be lengthened or shortened until the cam knocks off the steam hook at about half-

stroke, when the governor is resting on the stop. The stop should then be taken out from under the governor, so that it will drop, and the safety cam should then come round so as to prevent the steam latch from engaging at any point in the stroke. The valves are now set as nearly as can be done without the indicator. They are close enough to allow the engine to turn over under its own steam, and a diagram can then be taken, which will allow further adjustment.

With Two Eccentrics

When the engine has two eccentrics the exhaust and steam valves are driven independently, which makes the adjusting a still easier matter. The steam valves are set in the same manner as with the single eccentric, and the exhaust valves are adjusted separately by the marks on their own wrist plate. With two eccentrics the adjustments, being absolutely independent, can be made much finer than with the single one, because they are not limited by the effect of one upon the other.

Indirect Motion

The eccentric rod of a Corliss engine practically always drives a rocking lever, and it will depend upon whether the reach rod that drives the wrist plate is upon the same side of the fulcrum as the eccentric rod, or on the opposite, if the motion is direct or indirect. If the reach rod is pivoted upon the opposite side of the fulcrum of the rocking lever to that upon which the eccentric rod is pivoted, the two rods will have opposite motions. In this case the eccentric must be set behind the crank instead of ahead of it. This also applies to a piston valve which takes steam upon the inside of the valve instead of the outside. In this case the angle of advance will be towards the crank instead of away from it, or in other words, the eccentric will be just 180 degrees from the position it would occupy if driving direct.

We may sum up the setting of a Corliss engine in the following way. First adjust the reach rod so that the wrist plate has equal travel on the wrist pin. Then with wrist plate in its central position adjust the steam rods so that the steam and exhaust valves are in mid position. Turn the engine on the dead centre and move the eccentric around until the valve has the required amount of lead. Adjust the eccentric on the shaft. Adjust the governor reach rods so that the cam will release the valve at half stroke, when the governor is down on its stop. Take the stop out from under the governor and make sure that the safety cam throws the steam hook clear of the die when the governor is in this position. Make all fast and turn the engine over by steam, adjust the valves in the dash pot so that they pull the valve down sharply and take an indicator card.

Some Notes on Anhydrous Ammonia

By W. C. KLOTZ

MANY of those operating refrigeration plants, when asked what anhydrous ammonia is, may reply, "Why, it's the stuff we put into the freezing plant to make ice," and beyond a few fundamentals this possibly comprises their whole knowledge of this important industrial chemical, which they daily make use of in their routine work. Since it is well to have at least a fair knowledge about the materials one is working with a short discussion of the everyday characteristics and actions of anhydrous ammonia as it affects working conditions may be in order.

Two Greek words meaning 'without water" form the derivation of the term anhydrous, and so the meaning of the whole world is free from water. Strictly speaking, therefore, the name can be applied to ammonia either in gas or liquified form, but commercially it is used only in referring to the latter, viz., ammonia gas liquified under pressure.

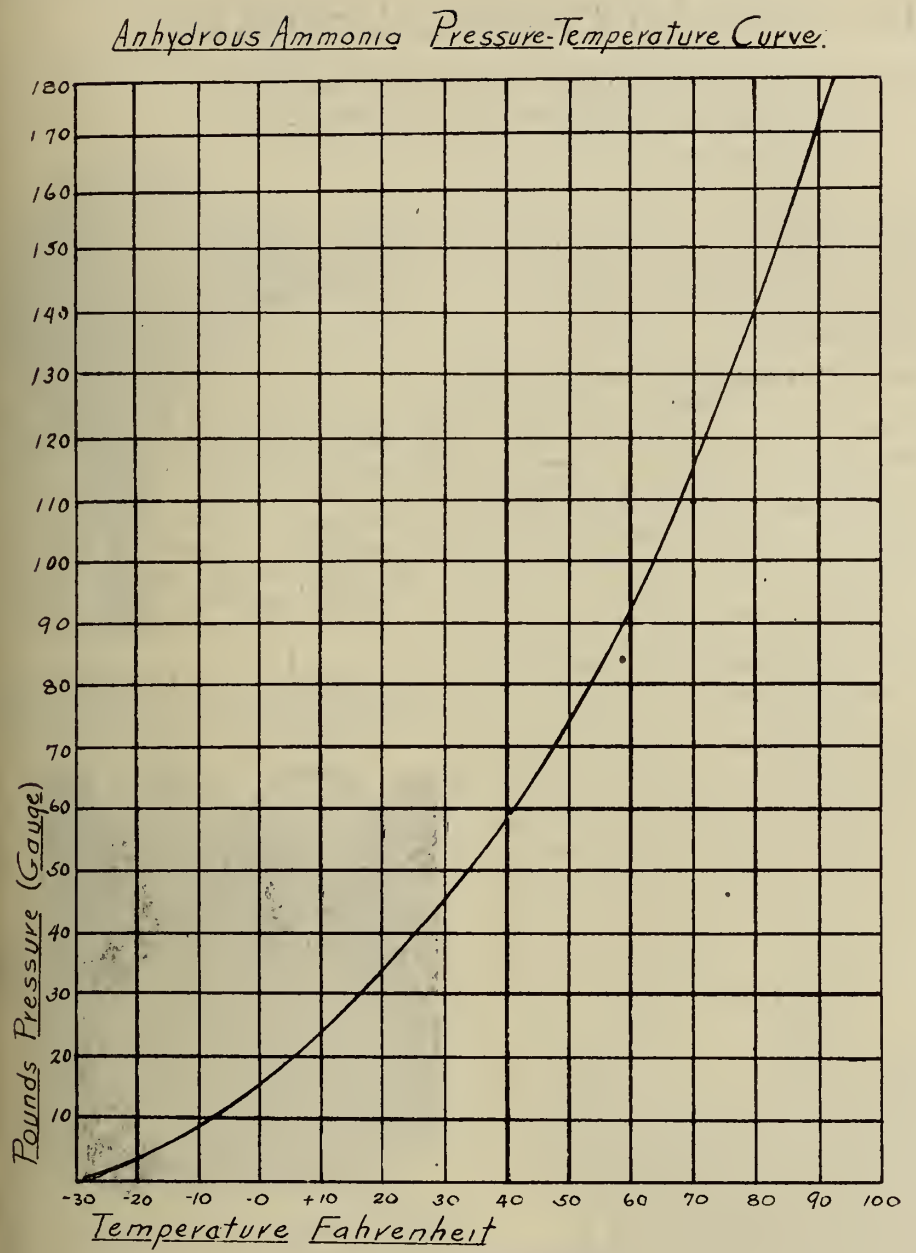
Under ordinary atmospheric pressure anhydrous ammonia boils at —28.5°F., and at —103.9°F. it freezes to a solid mass without any odor. Expansion into a gas increases its volume to the extent that one pound of the liquid at 70 deg. F. when allowed to evaporate would fill a room space of 22.6 cubic feet.

In appearance and action anhydrous ammonia is strikingly like water in many ways. It can be frozen to a white solid resembling ice, this can be melted by heat to a colorless liquid like water, and by application of more heat can again be vaporized to a white vapor similar to steam. It will dissolve sugar, sal ammoniac and such materials, and the solution can be evaporated, leaving the materials intact as before. Starch dropped into liquified ammonia will swell up very much like it does with water. But anhydrous ammonia can dissolve substances that water cannot. For instance, sulphur will dissolve slowly, forming a greenish liquid in the open, and purple under pressure, and rubber and gums are also acted on to a certain extent. Metals such as iron, aluminum, lead, nickel, etc., are unaffected by it while copper and zinc are more or less slowly attacked. Anhydrous ammonia is but an indifferent conductor of electricity, but presence of water in it increases the conductivity.

Although at —28.5°F. anhydrous ammonia exerts only atmospheric pressure, yet increase in temperature causes a rapid pressure rise, far more so than the proportional temperature increase. This can best be seen from the accompanying pressure temperature diagram illustration, in which the horizontal lines represent degrees Fahrenheit, and the vertical lines the gauge pressure. By following up the line for any given temperature until it meets the curve, and then drawing a horizontal line to the pressure scale, the corresponding pressure value can be at once noted. In order to raise the pressure by 20 lbs. from 0 to 20 (gauge reading) an increase of 34.5 deg. F. is necessary. To raise it by the same amount from 80 to 100 requires 10.5 deg. F., while to raise it similarly from 180 to 200 requires an increase of only 6 deg. F. As the pressure of ammonia in compression under average working conditions approximates the latter figures, the reason for care in the regulation of condensing apparatus becomes apparent.

If a current of air is passed through a flask of anhydrous ammonia the temperature will gradually drop away down to —112°F. from excessive evaporation. As this temperature is below the freezing point of ammonia, crystals of solid ammonia "ice" will soon commence to form and will again disappear as the liquid is allowed to warm up, melting in the liquid like ordinary ice.

As stated, anhydrous ammonia, boiling freely in the open air, will show a temperature of —28.5 deg. F., and this, under correct atmospheric pressure conditions, forms a good test of ammonia purity, but this does not mean that a thermometer placed in a flask of ammonia and left there will necessarily read —28.5°F. As a matter of fact, unless the contents are kept boiling the mercury will gradually go down to —34°F., or lower, according to the temperature of evaporation. Now if the flask is again made to boil by placing in cold brine, the temperature will once more rise to —28.5°F., and remain there as long as outside warmth is applied. Again, if we take a sample of anhydrous ammonia in a glass flask, and another in an iron cup, set them side by side, and insert a thermometer in each, the temperature of the glass sample will almost immediately commence to drop to about —34°F., while the iron one will remain for some time around —30°F. The reason is that the iron, being a conductor, will release heat readily to the evaporative requirement of the ammonia, keeping the temperature up, while glass, being a non-conductor, yields no heat to the contents, which consequently must get the necessary evaporative heat from wihin, and hence quickly falls in temperature. The same thing is true of anhydrous ammonia spilled on a piece of wood and a piece of iron. Although both samples are identical the spot on the wood will remain inert or dead, look like a water stain and feel damp to the hand for some time. while that on the iron will bubble and evaporate freely and quickly disappear. In more than one refrigeration plant where anhydrous ammonia has been allowed to drop on a wood floor and the apparent lifelessness of the liquid noticed, the conclusion has been arrived at that the ammonia was



TEMPERATURE PRESSURE CHART.

wet or otherwise faulty when such was not the case. In fact the presence of moisture in a sample of ammonia will actually increase the bubbling.

The presence of water, or soluble impurities, raises the boiling point of anhydrous ammonia according to the amount present. The following table gives the corresponding temperatures at which anhydrous ammonia, containing fixed quantities of water, will boil in the open under standard atmospheric pressure:

% Anhydrous	% Water	Boiling Temperature
100	0	—28.5°F
95	5	—22.0
90	10	—17.5

But while the 100 per cent. sample will retain a constant boiling temperature the others will not. When a mixture of anhydrous ammonia and water commences to boil the anhydrous will evaporate off, but not the water, hence the longer it boils the larger will be the proportion of water, and consequently the temperature will keep creeping up in proportion.

Also unless care be taken the thermometer readings may be decidedly misleading. As an example, two samples were set side by side in the writer's laboratory, in glass flasks, open to the air. One was in its original pure condition and to the other 5 per cent. of water had been added. A thermometer was placed in each flask. The pure sample was kept boiling by being placed in cold brine, and the diluted sample was left quiet. The readings of both thermometers were within one degree of each other, viz., —28, —29°F. In other words, both samples passed an approximate temperature test of pure ammonia, yet one was known to contain a large amount of foreign matter—5 per cent. water. Had the diluted sample been kept boiling, the temperature would have risen to —22°F., an ample assurance of the presence of foreign substance. The practical application of this is that an engineer, drawing a sample from his machine and relying on a temperature test without observing the proper conditions may easily come to the wrong conclusion that, since the temperature noted was that of a pure ammonia sample, the ammonia should be satisfactory, but as it will not do its work satisfactorily in the system the original lot must certainly have been bad.

These various conditions all depend on the ability of the ammonia to get heat to permit it to evaporate without drawing on its own contained heat, and while temperature and evaporative tests form a correct indication of its condition, care must be taken that wrong conclusions are nit deduced from the results obtained.

The injurious effects produced from ammonia laden air form a subject of much discussion and difference of opinion. While an excess of the gas is harmful, just as any other chemical gas would be, still small quantities in the air are harmless beyond producing temporary headaches and irritation in the eyes. Fortunately the very pungent nature of ammonia gas prevents prolonged breathing in any quantity and so acts as a rule as its own safeguard. Its strong odor at once gives warning of its presence even in minute quantities, for as little as 0.05 volumes of ammonia per 1,000 of air can be detected in a room; 0.3 volumes per 1,000 of air can be endured for some time without bad results, but 2 volumes per 1,000, when inhaled for any length of time are dangerous, since they produce irritation of the lungs and other breathing organs with danger of consequent inflammation. They do not, however, when merely inhaled, affect any other part of the body in consequence.

HEATING PARLIAMENT BUILDINGS

(Continued from page 25)

each, and there is an engineer in charge on duty all day and one all night. There is ample opportunity in the summer when Parliament is not in session to carry out all the repairs that may be necessary.

Steam is also supplied to the parliamentary kitchens for cooking purposes, and there is, of course, an enormous demand for hot water for domestic purposes in such a huge building. The central plant takes care of it all and to everybody's satisfaction.

It is cause of satisfaction to think that this big job was designed by a Canadian consulting engineer and carried out by Canadian contractors. As much of the material as possible was obtained in Canada. It should make those among us who think they must always go to the United States for a consulting engineer pause and consider the engineering talent available at home. Those engineers who are going to attend the C.A.S.E. convention in Ottawa this year should certainly not miss the opportunity to visit this interesting plant.

Some Results with Mechanical Stokers

This Article is the Second One on This Subject, and in it The Various Methods of Installation are Described and Illustrated

By ROBERT JUNE

SOOT as found in steam boilers varies considerably in appearance and composition, depending upon the grade of coal burned, conditions of combustion and part of the furnace from which the sample is taken. Nearest the fire the deposits formed consist largely of ash. Analysis of samples of soot, taken from a boiler, shows in addition to the "pure soot" the presence of silica, alumnia, iron oxide, various alkalies and sulphur dioxide.

In all but the coolest portion of the setting, soot is usually gritty in texture. The grains may be as large as medium size sand or as fine as cigar ash. These particles are in a plastic state when they leave the furnace, and striking the boiler they adhere to the

FIG. 1 — Typical installation of Soot Blower System on a horizontal return tubular boiler. Door is shown transparent in order to show piping and method of operating main blower valve from floor.

tubes. If this deposit is not removed frequently it quickly increases in amount and changes in character. The carbon burns out in part and the mass cements together. The repeated reduction in heat-absorbing surface increases the temperature of the flue gases so that the process of cementation is continuous and constantly increasing in intensity. An extremely hard, clinker-like formation results. In a short time the tubes in some portions of the boiler are thickly coated, thus materially reducing its capacity.

In our discussion last month we dealt with figures of actual tests conducted to determine the efficiency of mechanical soot blowers with various types of fuel, such as anthracite and bituminous coal, pulverized fuel and oil. We found that mechanical soot blowers would effect a saving of 4 to 8 per cent. in fuel and also effect an important reduction in labor, so that the importance and value of mechanical soot blowers was self-evident.

The Five Essentials in Preventing Soot Waste

The five essentials in preventing soot waste are:

1. Frequency of cleaning in order to minimize the cumulative effects of increasing deposits. Tubes should be cleaned three or four times in twenty-four hours.

2. Thoroughness of cleaning, in order to maintain high furnace and boiler efficiency and prevent the corrosive effects of soot accumulation.

3. Availability of system. The soot cleaner system should be instantly available, automatic in action, capable of rapid operation.

4. Durability of system. The blower units should be so designed and constructed that they will withstand the stress of hard service without the necessity for frequent repair or replacement.

5. Economy in operation. The soot removing system should be cheaper in operation than hand blowing; it should be so installed as to prevent the entrance of cold air into the furnace during its operation: it should not interfere with the operation of the boiler; it should pay for itself from an investment standpoint.

Soot Blowers for Horizontal Return Tubular Boilers

Soot blowers were first manufactured on a commercial basis for Scotch marine boilers on the Great Lakes. The blowers were what is known as the "rear end" type, being installed through an opening in the water leg in the rear. It was only natural, therefore, when soot blower manufacturers began to develop equipment for stationary horizontal return tubular boilers that they should start in by adopting the rear end blower on Scotch marine boilers for this purpose.

For a good many years it was the universal practice of all soot blower manufacturers to make only rear end equipment for horizontal return tubular boilers. The rear end blower had numerous disadvantages, however, and about eight to nine years ago soot blower manufacturers generally began to produce front end blowers. While rear end blowers can still be purchased from one or two of the older manufacturers, they are seldom recommended and practically every manufacturer of this type of equipment manufactures and recommends the front end blower to the exclusion of the older type.

A typical installation is shown in Fig. 1. This consists of a blower arm inset with Venturi nozzles and placed at the front end of the boiler. The position and arrangement of the blower are such that when it revolves the nozzles direct the steam jets directly into every tube of the boiler. With an initial pressure of 150 pounds this steam is shot from the nozzles at a velocity of approximately 2,700 feet per second. As can be imagined, the effect is to remove every bit of the soot and fine ash deposit.

The blower unit is attached to the door, and when the door is opened the entire mechanism swings with it, leaving the boiler ends free and clear for inspection repairs, etc., and exposing and making easy of access any part of the blower.

FIG. 2 — Detailed view of the revolving unit installed in a horizontal water tube boiler. The method of supporting blower units on tubes, and the position of the units and nozzles relative to the tubes, is practically the same on all types of horizontal and vertical water tube boilers to which this system can be applied. Notice there is a Venturi nozzle for EVERY space between the rows of tubes.

Both the tubes and the combustion chamber are cleaned at the same time. The sweeping of the arm as it swings in a complete circle allows the steam to be shot directly into the tubes on a straight line, and the corner tubes are taken care of with the same thoroughness as the centre ones.

The blower being at the front end of the boiler, and the entire mechanism controlled from the outside, it is easy to get at and operate, making the cleaning of the boilers three or four times a day a simple process. Each operation will consume only about a minute's time.

One of the most important advantages attaching to the use of mechanical soot blowers is the absolute exclusion of cold air from the boiler. The boiler doors are always shut tight when the blowers are in operation, and it makes no difference what load the boiler is under. In

FIG. 3—Head of Model "G' Unit used on water tube boilers. Note the strong symmetrical construction. The use of the gooseneck permits the steam main to be brought close to the boiler setting, thus adding greatly to the appearance of the installation.

fact, the more the boilers are being forced the more need to clean the tubes. This cleaning cannot be done with a hand hose without reducing the load. It can be done in a few moments right at the peak of a load with mechanical soot blowers and all of this is accomplished without any reduction in efficiency caused by admission of air.

Equipment for Water Tube Boilers

For cleaning water tube boilers of the usual horizontal type, vertically baffled, and for cleaning most types of vertical boilers and economizers, the equipment supplied by the principal manufacturers commonly consists of a permanent installation of revolving units located at various points in the passes of the boilers. In a typical installation, Figs. 2 and 3, the equipment consists of five principal elements, as follows:

1. A head through which the steam passes from the main soot blower supply line when the valve is opened. The head is the foundation element to which the other elements are attached.
2. A wall box which is bricked into the setting. The box supports the unit, and is so constructed that the blower can be turned freely without admitting air to the inside of the setting.
3. A blower element running crosswise of the bank of tubes and consisting of a small header with nozzles so placed as to discharge steam between the boiler tubes.
4. A sheave or hand wheel by means of which the blower element is rotated.
5. Bearings attached to the boiler tubes which support the blower element and permit it to revolve freely.

Soot Blowers for Horizontal Water Tube Boilers

The general arrangefent of the units in horizontal water tube boilers consisting of a single bank of tubes is shown in Fig. 4. It will be noted that a unit is shown over the arch at the bottom of the first pass. This is extremely important inasmuch as this is the point where the gases first strike the boiler and where the largest deposits of soot and ash are to be found. This is also the hardest working part of the boiler, as the temperatures are highest here and the transfer of heat to the water is most rapid.

In order to maintain this rapid transfer of heat, the deposits of soot and ash must be removed at frequent intervals. As the temperatures are extremely high at this point, the problem has been presented to soot blower manufacturers in designing a unit which would stand up and perform its functions satisfactorily. The problem has been solved by treating the unit by a special process known as "Calorizing" to prevent the burning of the metal at high temperatures and by placing the unit close against the front header of the boiler behind a baffle so that the blower unit will stand up in this location for six months to three years and in some cases even longer. As the cleaning of this part of the boiler is of vital importance, power plant operators have found that they can well afford to replace the blower pipe of this unit from time to time as conditions warrant.

The second unit is located at the top of the first pass in a position which enables it to clean the superheater as well as the boiler tubes. The frequent cleaning of the superheater is essential to the maintenance of high and uniform steam temperatures and an individual soot blower unit for this purpose is frequently provided. The remaining units in the boiler are located as strategic points in the passes.

Soot Blowers for Vertical Water Tube Boilers

The world's largest boilers are of the vertical type, and it is a notable fact that these large boilers almost without exception are equipped with mechanical soot blowers. Proper arrangement of the units is one of the most important factors in the success of these installations. In the Stirling, Connelly, Kidwell and similar boilers the thorough cleaning of the tubes at the bottom of the first pass is secured by the installation of calorized units. Temperatures are high at this point and the calorized metal withstands high temperatures without oxidizing.

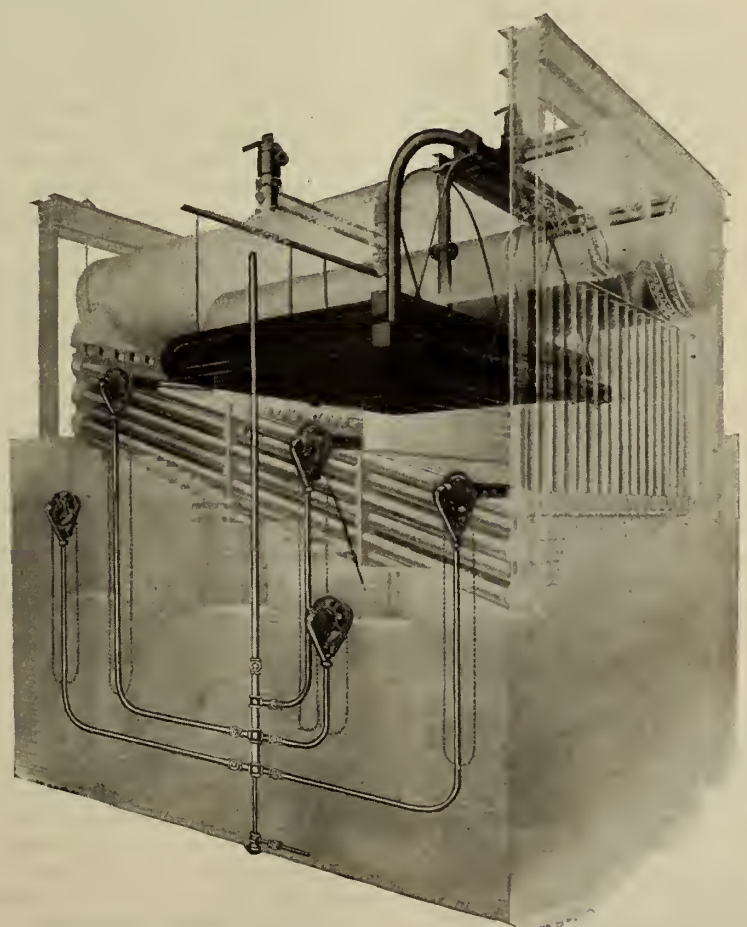


FIG. 4—APPLICATION OF THE MECHANICAL SOOT BLOWER SYSTEM TO HORIZONTAL WATER TUBE BOILER, VERTICAL BAFFLE TYPE WITH SUPERHEATER.

One of the principal requirements of a successful soot blower installation for vertical boilers is that the system employed shall allow the steam jets to play effectively over the whole gases by unnecessary obstruction. The number and location of the units in vertical boilers varies with the different sizes and types of generators. The number of units will run from five in the small Stirling boilers without superheater to thirty-two in the big W type of 2,365 h.p. such as are used at the plant of the Detroit Edison Co. and other large central stations.

With Wicks boilers, Fig. 5, the problem of design is complicated by the fact that economy in space is one feature of Wicks installation and that the boilers are therefore often set in solid batteries, rendering it difficult to get at the lower part of the rear pass.

Tubes over the arch are cleaned by means of a special removable unit. This unit consists of a multiple jet blower element, with one nozzle for each row of tubes. A universal joint of steam-tight design permits easy operation of the unit and insures thorough cleaning of this section of the boiler. The unit is permanently secured to the boiler shell and when not in use can be withdrawn from the tube space out of the heat—a desirable feature in such installations as have temperatures in excess of 2,000 degrees.

Economizer Installations

The same type of units used to clean boilers are now being generally used for the purpose of removing soot and ash deposits from economizers, whether the latter are an integral part of the boiler

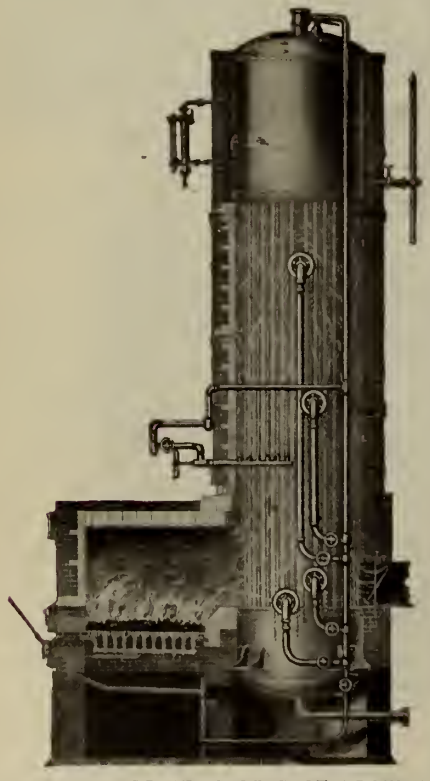

FIG. 5—INSTALLATION OF SOOT BLOWERS ON WICKS VERTICAL BOILERS.

FIG. 6—INDEPENDENT TYPE OF ECONOMIZER EQUIPPED WITH SOOT BLOWERS INSTEAD OF SCRAPER MECHANISM.

or independent units. Fig. 6 shows the method of installation. The arrangement provides for units extending from front to back of economizer centrally located between the top and bottom and spaced four or five rows of tubes apart.

We have stated that soot blowers are going into use on economizers, replacing the old type scraper mechanism. The advantage of soot blowers as compared with the scraper are:

A. Elimination of air infiltration. For every 10 to 16 tubes, depending upon the capacity of the economizer, there is a chain provided for the raising and lowering of the scrapers. These chains pass through holes in the top of the economizer. As these holes are always open, air infiltration is a constant source of loss—a loss which is eliminated when soot blowers are installed.

B. One of the conditions always encountered in some degree in economizer installations is the piling up of soot on the bottom headers. While it is true that a space is provided between the headers which would seem to be ample for the soot to fall through into the soot chamber, yet quantities of it are always building up in the space between the headers and eventually bridging over. As a result the action of the scrapers is interfered with and the efficiency of the economizer is affected by reason of the accumulation. This difficulty is always removed by the use of soot blowers.

C. The scraper mechanism takes from 2 to 5 h.p. of electric power to operate. There is constant charge for power. Scraper maintenance is also one of the most costly features of economizer installation. In addition to the cost of operation and maintenance there is also the handicap of making repairs to the tubes of the economizer. While soot blowers require some operating charges, these charges are very low when compared with scrapers, and in addition the economizer is cleaned more efficiently.

For hollow stay bolt boilers the soo blowers consist of two main pipes fron which extend many branch pipes carry ing Venturi nozzles. One of thes nozzles enters every hollow stay. Th system is so arranged that it clears th hand-hole yokes, permitting them to b removed, and thus making the tubes eas ily accessible for turbining or repair without disturbing the blower in th least. The entire equipment is perman ently installed on the front water leg o the boiler and is operated by two valve only, from the front.

Where boilers are built with horizon tal baffles, a number of the nozzles ar extended over the baffles for distances o from two to eight feet, thus insuring high degree of efficiency in cleaning In addition to the use of blower nozzle extending from the stays, it is at time found possible to equip boilers of thi type with revolving units as well, an this combination equipment offers th most satisfactory method of securin high cleaning efficiency in this type o boiler.

Recent Advances in Design and Con struction

One of the most important recent ad vances in design and construction fron the point of view of increased efficienc is the development of the vertical heade type of installation, Fig. A. This de sign presents many advantages as com pared to the old practice of placing th header in a horizontal position whic may be summarized as follows:

1. Increased effective pressure o steam at blower nozzles, due to the elim ination of a number of right angle joint and the reduction of friction at the fit tings.

2. Permits free expansion of all rise pipes, thus preventing any possible bind ing of the units.

3. Eliminates a number of screw joint with consequent reduction in opportun ities for leakage to develop.

4. This form of construction gives

much less interference with doors, etc., than when horizontal header or right angle joints are employed.

5. Presents much better appearance mechanically.

6. Permits the use of a much shorter header.

7. Valves are concentrated at one point, facilitating rapid operation.

8. Assures thorough draining.

In addition to these special merits, it can be installed as quickly as the horizontal header with its right angle joints, and the cost is, if anything, but little more.

Welded Nozzles

When nozzles of Venturi section were developed, the problem of high velocity as far as soot blowers were concerned was solved for all time. The method of fixing the nozzles in the blower elements, however, has been subject to considerable improvement in the past few years. Originally, nozzles of all soot blower units were simply screwed in

FIG. 7—INSTALLATION OF SOOT BLOWERS ON WATER TUBE BOILER WITH HOLLOW STAYS.

place. Experience showed that the hot gases were continually attacking the threads and that oxidation at this point was much more rapid than elsewhere, with the result that after the blower elements had been in use but a short time the nozzles became loose and in the course of time dropped out, thus rendering the blower element ineffective. To overcome this difficulty, a method of welding the nozzles in place has been developed and is now in commercial use.

The same trouble which developed with screwed nozzles developed with the screwed plugs which were originally used to close the ends of soot blower elments; that is, the gases attacked the threads, with the result that the plugs became loosened and at times blew out. In order to overcome this difficulty, caps were welded on the ends of the blower elements. This construction has, however, recently been modified and greatly improved by placing a disc of steel inside the blower element, then swaging the end, thus partly closing it, and then welding the plug in place, completely closing the end so that there is no possibility of the plug being blown out by the steam.

Probably no feature of soot blower construction has been subject to so much study and improvement as have the bearings which support the units inside the boiler. These bearings were originally made of cast iron, but in the last year a special type of steel bearing has been presented which has innumerable advantages over the old style cast iron bearings. The advantages of the steel bearing are the closer grip on the boiler tube, less transfer of heat, less likelihood of working loose from the boiler tube, etc.

HAMILTON NO. 2 C.A.S.E.

Hamilton Lodge No. 2 held an open meeting on 4th April. Mr. Church, of Toronto, representing Darling Bros., was present and gave a very interesting talk, explaining the slides as shown on the screen. Darling Bros.' steam specialties were the topic of the evening. A vote of thanks was tendered Mr. Church, also Darling Bros. for their kindness in loaning the slides. Hamilton No. 2 is endeavoring to hold up their end of the educational programme. First meeting in May we are having Mr. Parkins, a representative of Canada Metal Co., give us a talk on babbitt metals; also Mr. McDonald, who is at present in Hamilton installing automatic smokeless furnaces. First Monday in June, Coal and Its Origin and Mining of Same, by Mr. S. Gill.

OTTAWA LODGE C.A.S.E.

Ottawa Lodge No. 6 C.A.S.E. held an open meeting in their (St. George's) hall on Thursday evening, April 28, which was well attended. The programme for the evening was a paper on combustion given by Bro. G. I. Scott, chief engineer for the Ottawa Electric Co. Bro. Scott handled the subject with great care to explain the technical points, making the subject clear to all present.

Bro. Scott also gave a lecture on the boiler assisted by Bro. C. V. Clarke, manager Ottawa branch of the Darling Bros. The lecture was illustrated by lantern slides. That the meeting was a success is judged by the number of applications received for membership for the first meeting in May.

Ottawa Lodge is looking forward to the convention to be held by the Grand Lodge in Ottawa on June 27, 28, 29 and 30, which they hope will be a huge success.

They hope to have one of the finest power exhibits ever shown by the order.

LONDON LODGE, C.A.S.E., No. 30

The London Lodge, C.A.S.E., and a number of their friends and relatives held a very successful social evening recently, about one hundred and twenty people being present. The evening was devoted to cards and dancing, and everybody enjoyed it to the full. The London lodge has had a very successful year, the number of new members being twelve. From time to time lectures with lantern slides to illustrate them have been given and these have contributed materially to the interest shown in the lodge.

PERSONAL

J. O. B. Latour, chief engineer for the General Accident Assurance Co. of Canada, has resigned his position and is taking up a similar position with the Employers Liability Assurance Corporaton. Mr. Latour, who is one of the best known engineers in Canada, joined the old Canadian Casualty and Boiler Insurance Co. in the year 1903 as expert engineer and inspector. He remained in that position until October, 1911, when he took over the position of chief engineer, vice A. M. Wickens. In 1916 the Canadian Casualty Co. was taken over by the General Accident Co. and the name changed to the latter company's, Mr. Latour still retaining his position.

* * *

During the intervening years Mr. Latour has seen the boiler business gradually expand until there are now eight companies in Canada carrying these lines. During his connection with the company the revenue from boiler business has increased by nearly 200 per cent. and the staff of inspectors increased likewise. Mr. Latour's many friends in the engineering world will be unanimous in wishing him every success in his future sphere of action and congratulate his new employers on securing his wide experience and undoubted engineering ability. Mr. Latour will be succeeded, we understand, by W. B. Roberts, who has been on the staff for some years. Mr. Roberts is a native of Liverpool, England, and served his apprenticeship to marine engineering at the works of Messrs. Fawcett, Preston & Co., one of Liverpool's famous old engineering establishments. Mr. Roberts served in the Royal Navy during the war, returning to Canada in 1919 with the rank of engineer lieutenant commander. He holds the British Board of Trade certificate of extra first class and has had a wide experience both in the practical and commercial side of engineering. He was chief inspector for Alberta and Saskatchewan for the General Accident Co. for some time, and will bring a good insurance knowledge as well as engineering ability to his new position.

ERROR

In our issue of April 5, answering the question on boiler heating capacity, on page 35, the number 162 degrees should have read 102 degrees.

Vertical Gas Engine for Generator Drive

British-Built Gas Engine Developed For Special Purpose—Comparison of Vertical and Horizonal Engines—Turning Effort And Cyclic Irregularity—Details of the Engine

THE extremely high initial cost of all classes of fuel continues to influence that of iron, steel and other industrial products. Furnace coke, both in its manufacture and again when used in the blast furnace, gives off large quantities of gas rich in by-products and valuable as a means of generating power. The efficient utilization of these gases in large gas engines is a problem which has been neglected in the past. It is only now, when faced with the growing scarcity and high market value of our natural fuel resources, that we begin to consider methods for their utilization to the best possible advantage.

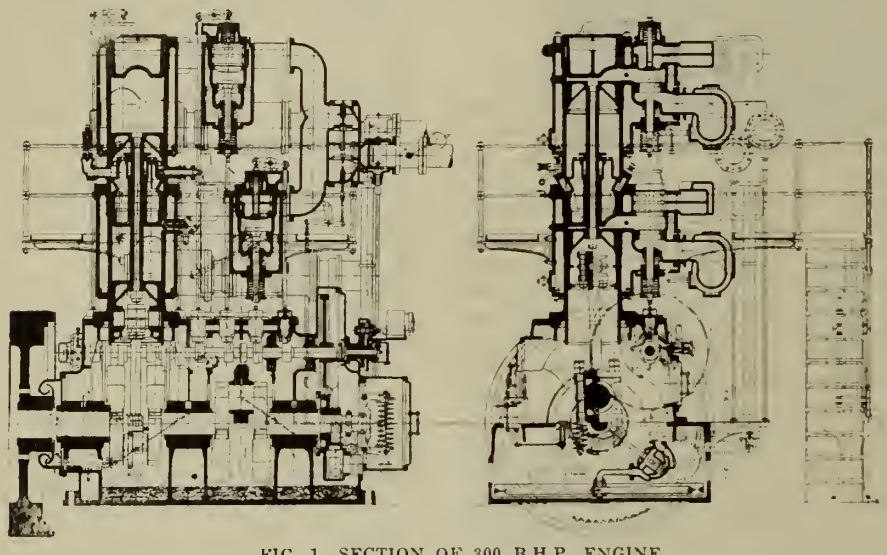

FIG. 1—SECTION OF 300 B.H.P. ENGINE.

During the past ten years marked improvements have been made in gas engine design, with a view to producing a prime mover that will adapt itself to the varying loads required, and at the same time be economical in gas consumption. These improvements are the result of co-operation between some few pioneers of the coal, coke, iron and steel industries, and gas engine manufacturers. The work has been carried out on very practical lines in collieries and ironworks, where there is not a great deal of scope for scientific research, owing to limitations both in the number of staff employed and the expense involved. Valuable data on the subject have been contributed from time to time in papers which have been read before the various societies, etc., from which running costs and general comparative cost figures can be obtained. It is therefore unnecessary to bring these forward here, but rather to explain the development of the existing vertical tandem gas engine.

In the past, when running large gas engines on waste gases, enough importance has not been attached to the maintenance of a constant supply of clean gas at a constant pressure and heat value. These items are dependent to a great extent on the type of ovens, furnaces and cleaning plant employed. To maintain constant pressures the most satisfactory results have been obtained when small gas holders have been employed to control the supply to the engines.

Coke Oven Gas

The greatest difficulty encountered when dealing with coke oven as compared with blast furnace gas has been the fact that the former contains roughly 50 per cent. of free hydrogen by volume and 25 per cent. of marsh gas whereas the latter only contains from to 2 per cent. of hydrogen and no marsh gas. Their calorific values are:

Coke oven gas 420 to 460 B.t.u. per cubic foot.

Blast furnace gas 90 to 100 B.t.u. per cubic foot.

When using a high value gas in an engine it is usual to reduce the compression pressure and retard the point of ignition, in which case the engine governor independently controls the quantity of air and gas required for a given load but has no control over the quality of the gas itself. To overcome this difficulty a special device has been developed by the National Gas Engine Co., Ltd. whereby a quantity of cooled exhaust gas is returned to the engine governor. By referring to Fig. 2 it will be seen that the exhaust gas is mixed with the incoming high value gas around the

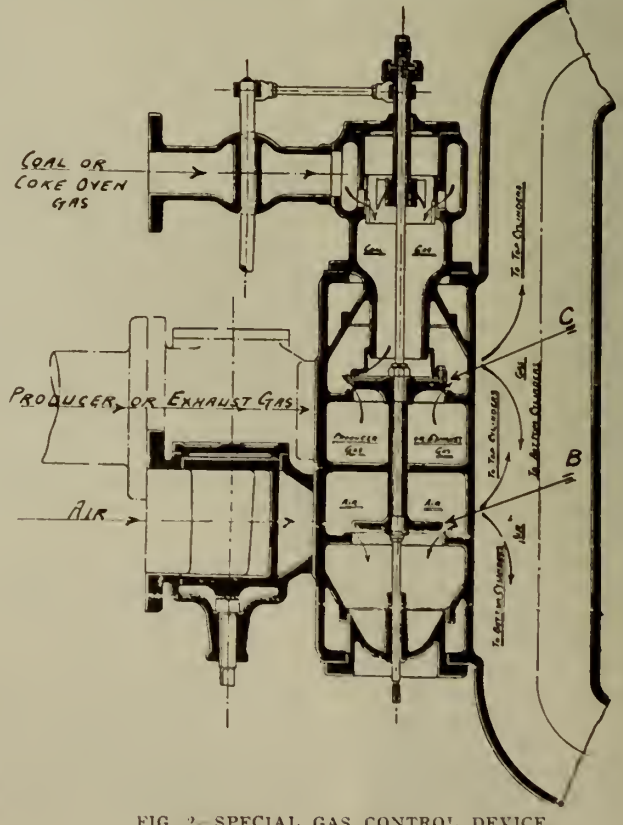

FIG. 2—SPECIAL GAS CONTROL DEVICE.

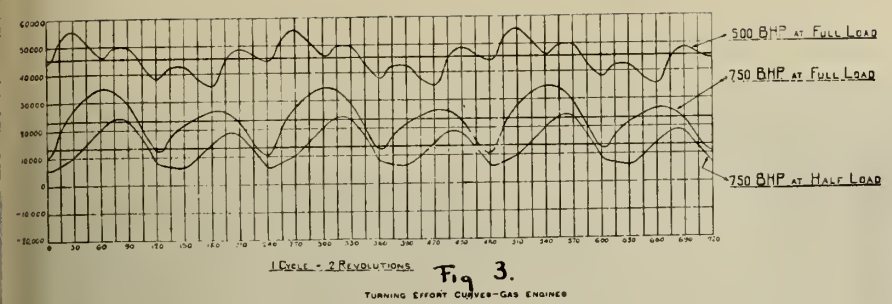

Fig 3.

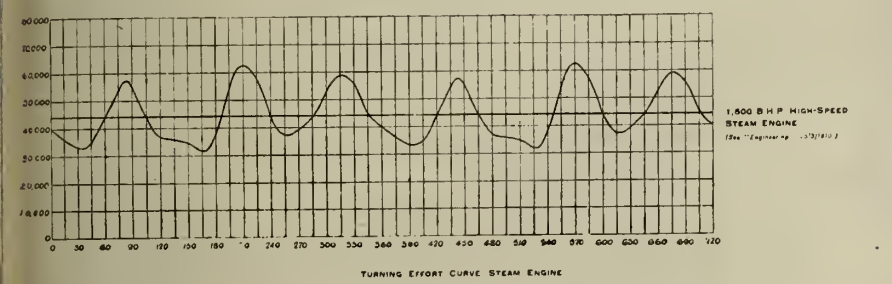
Turning Effort Curves—Gas Engines



Turning Effort Curve Steam Engine

Fig 4.

throttle valve seat C, independently from the air, which is controlled by the throttle valve B. The heat value of the resultant mixture (i.e., gas proper and exhaust gas) is then say 130 B.t.u. per cubic foot. This reduction in value from 460 to 130 B.t.u. per cubic foot allows the engine compression and ignition timing to be that required for a gas of low heat value such as producer gas.

This type of governor is now adapted to all National vertical tandem engines which are running on high value gases. Since the compression pressure is the same as that required for producer gas, the arrangement can be used as a change-over gear from town's to producer gas, or vice versa, and the change-over can be made when the engine is on full load without any indication of the change on the tachometer or switchboard, when driving an electrical generator. The application of this type of governor shows marked improvement over the standard type of throttle governor using high value gases, both in economy and in the satisfactory running of the engines on varying loads.

Blast Furnace Gas

The use of blast furnace gas for the production of electricity is slowly but gradually becoming adopted. This to a great extent is due to the improvements in design of cleaning plants. The Halberg Beth Dry Filter Plant, although expensive in first cost, will reduce the dust contents of the gas to about 0.001 gramme per cubic metre, which means that the gas is frequently cleaner than the surrounding atmosphere, while large quantities of potash are recovered as a by-product. Wet cleaning plants appear to be giving satisfaction, too, though they do not lend themselves to potash recovery. Electro-static cleaning plants have been in use in England for some time, though for rough cleaning purposes only. A great deal is expected of this method in the near future. It must not be forgotten that the gas must have the existing sensible heat considerably reduced before it can be used in an engine.

Comparison of Vertical and Horizontal Engines

Before proceeding to a description of a vertical tandem engine, it may be of interest to give some of the reasons for adopting this design in preference to the large horizontal type of the same power. One of the chief reasons is the absence of water-cooled moving parts in the vertical tandem machine.

Water-Cooled Moving Parts.—Gas engine pistons, piston rods and exhaust valves for cylinders above a diameter of approximately 25 inches require to be water-cooled. Quite apart from the difficulties in design which exist when allowing for vapor pockets, proper distribution and circulation of the water, complications arise as a direct result of water-cooling, such as the following:

The small amount of space available necessitates the water being of a suitable nature, i.e., it must not contain acid or alkali within certain limits, and efficient arrangements for cleaning must exist in order that the dirt and scale accumulating in the jacket spaces may be removed with comparative ease and in a reasonably short time; the temperature of the cooling water employed must be such that condensation is avoided on the rods and pistons before starting and after stopping; the difficulty of making satisfactory water-tight joints to prevent the leakage of water on to lubricated surfaces, which very often causes serious trouble; and the connection between the internal distributing pipe, to ensure circulation, and the piston rod, is subjected to great stresses on account of the existing forces of inertia.

Weight of Reciprocating Parts.—On large four-cycle double-acting horizontal engines (two cylinder in tandem type) the pistons should not be supported by the surface of the liners, nor the piston rods by the stuffing boxes. To avoid this in practice the rods are turned with their centre lines curved, to compensate for the weight of the pistons. All this weight then falls on the slipper guides. The time required to make adjustments to the working parts of a large horizontal engine is very considerable, due to the fact that these parts are of necessity heavy, and are difficult to handle even with the use of a crane.

Spare Parts.—The cost of spare parts is greater for the horizontal engine than for a multi-cylinder vertical engine, since the latter are standardized and produced in quantity, besides being smaller and more easily handled.

Electrical Generators.—The cost of electrical generators is also greater for the former owing to the difference in engine speeds, the one being run at 80 to 90 r.p.m., while the vertical engines run at between 200 and 300 r.p.m.

Turning Effort and Cyclic Irregularity

Parallel Operation of Alternators.—All alternators have a natural periodicity, depending upon the electrical design of the machine and the load to which it is subjected, and it is essential that deviation from perfect rotation should not exceed 2½ to 3 electrical degrees. It will be easily realized therefore that for an alternator with a large number of poles the permissible fluctuation is much more limited for a slow speed than for a high speed machine. The torque diagram of a steam or gas engine can always be represented as a series of waves irregularly formed, but nearly

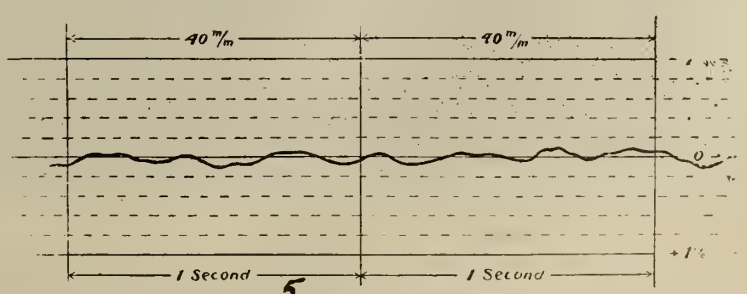


Fig 5 Tachograph Curve.

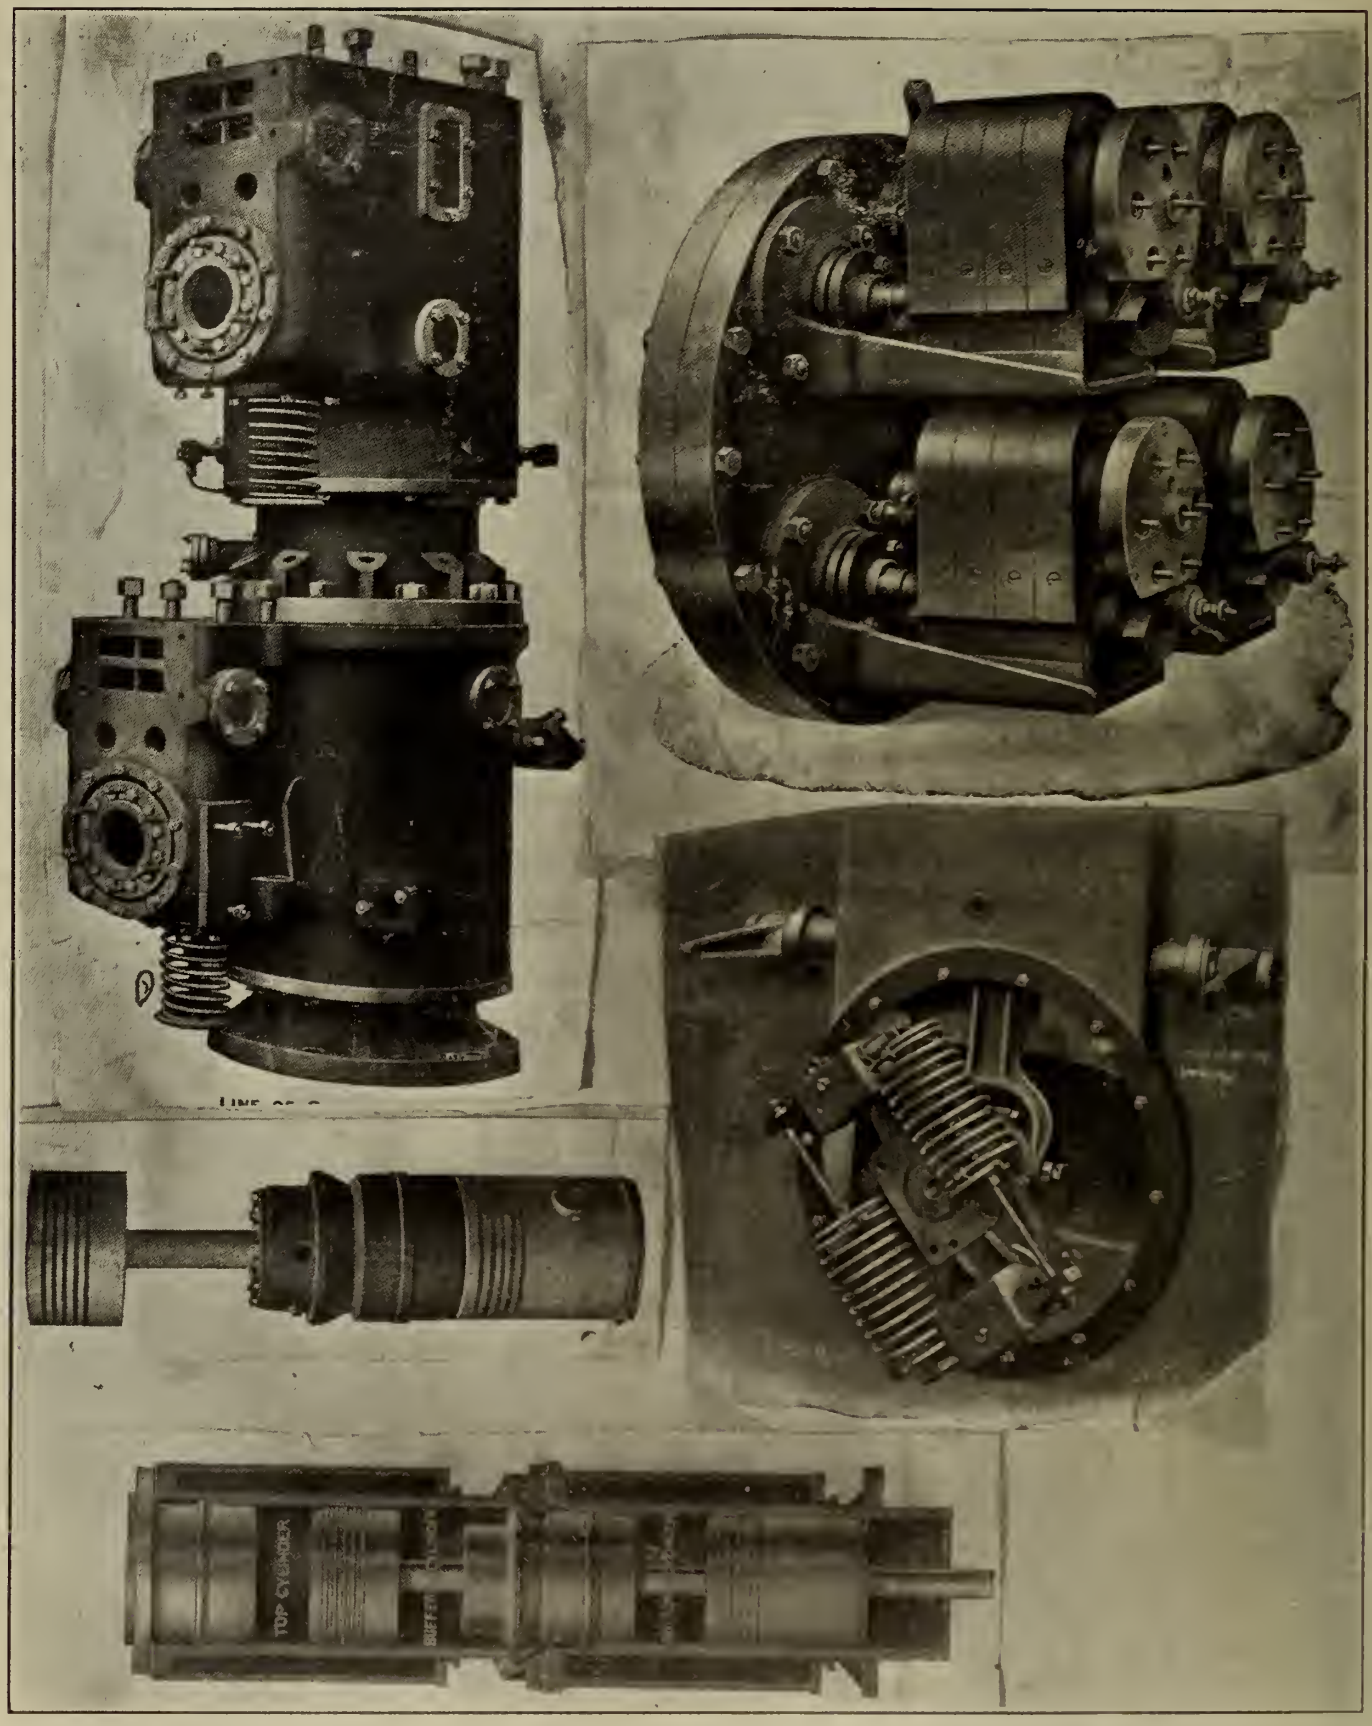

FIG. 6—CYLINDERS IN TANDEM. FIG. 7 SECTION OF CYLINDERS. FIG. 8—TOP AND BOTTOM PISTONS. FIG. 10—GOVERNOR. FIG. 11—IGNITION.

regularly repeated at constant intervals. (See Figs. 3 and 4.)

The impulses per revolution are, of course, the main factors that determine the flywheel effect if the flywheel is laid out for any standard cyclic irregularity.

If we consider the time of one or two revolutions as a fundamental period it is found that in all well-balanced reciprocating engines harmonics exist depending for their order upon the number of cranks of the engine. The value of the harmonics, although they exist, can be almost entirely ignored as far as hunting is concerned. The important fact is that, unless special precautions are taken, a fundamental wave will exist.

The National vertical tandem engines are designed, when required for alternator work, to have a cyclic irregularity of 1/250. Sufficient flywheel effect is allowed for in their design to easily cover this, and at the same time be

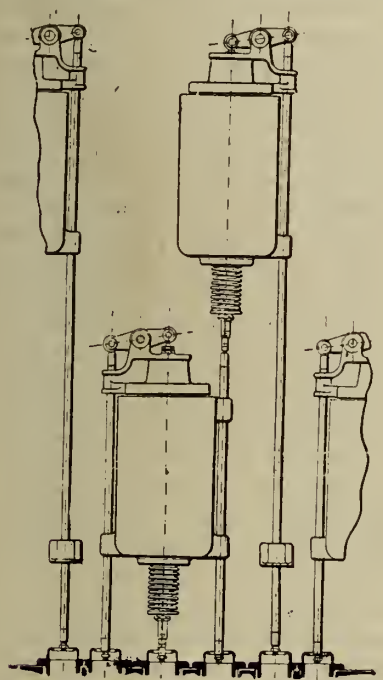

FIG. 9—ARRANGEMENT OF VALVES.

within the limits of 2½ electrical degrees from a standard flywheel. This is very much easier to do with a high speed than with a low speed alternator. Fig. 5 represents a tachograph curve from a vertical tandem engine, from which it will be seen that the cyclic irregularity, taken over the extreme points on the curve, is approximately 1/500.

The "National" Vertical Tandem Gas Engine

For the purpose of description and illustration a sectional arrangement of a 300 B.h.p., 2-crank, 4-cylinder engine is given in Fig. 1. The larger units, except in detail, are similar to this in design. The engines are built in standard sizes from 300 to 2,000 B.h.p., with 2, 3, 4, 6 or 8 cranks. They operate on the "Otto" four-cycle principle, and each pair of cylinders is arranged in tandem over one crank. (See Fig. 6.)

Cylinders.—A difference in diameter is made between the bore of the top and bottom cylinders, sufficient to allow of a cone seat being made in the top of the lower cylinder. The intermediate head or cover for the bottom cylinder makes a joint on this and is secured by "pole-screws" passing through the flange of the top cylinder on to an angular face around the intermediate head. (See Fig. 7.) A similar joint is made by the top cylinder cover.

Pistons. (See Fig. 8.)—The pistons, both "top" and "bottom," are secured together by means of a bolt of chrome nickel steel passing through a hard cast iron piston rod sleeve. This sleeve acts as a distance piece transmitting the thrust of the top piston to the lower piston, the steel bolt taking the tensile stresses. After being assembled the necessary working clearance is given to the line of pistons in the grinding machine.

Operation.—The tandem arrangement of pistons with an explosion on the top of the upper and lower pistons alternately, together with the number of cranks, gives an even turning effort. Smoothness of running is also the result of cushioning on every "up-stroke," by the compressions of the mixture taking place alternately in the top and bottom cylinders, and on every "down-stroke" in the spaces between the top pistons and intermediate heads. Metallic packing for the piston rods is secured in the top of each intermediate head. The packing is surrounded by the water jacket of the head and is supplied with lubricating oil under pressure.

A line of pistons, consisting of top and bottom pistons secured together, intermediate head and connecting rod, can be withdrawn for inspection and cleaning after removing the top cover, securing nuts and pole screws, water connections and crank head nuts. The whole is withdrawn through the top cylinder by securing a clip to the top piston.

Operation of Valves.—The inlet valves, in their respective cages, are secured in positions directly above the exhaust valves, and in order to give ease of access the valves in the top cylinders are "staggered" in relation to those in the bottom cylinders. (See Fig. 9.) This arrangement allows of a direct lift from above, thus facilitating their removal for inspection. The valves are operated by push rods and rocking levers, the exhaust valves being arranged vertically over their respective cams.

Governor.—The engine is controlled by a centrifugal governor mounted on the crankshaft (see Fig. 10), which controls the quantity of mixture admitted to the cylinders. Mixture of "gas" and "air" does not take place until the inlet valves open in the cylinders, the two being governed independently, and entirely separated from one another by a division in the manifold induction pipe.

Lubrication.—Lubricating oil is drawn from strainers in the bedplates, each lying in its own trough, into which the oil flows as it drains back from the crank pits. By this means the bulk of dirty oil is isolated from the strainers. The strainers can be withdrawn one at a time without interfering with the running of the engine. A valveless double acting pump delivers the oil at a pressure, which can be regulated, to the oil cooler and engine bearings. The oil supply to the crank head bearings passes through holes drilled in the crankshaft to the crank pin and up through the centre of the connecting rod to the piston pin. For a large installation of more than one unit, or a single unit of 1,000 k.w. and above, the pump, strainers and coolers are separated from the engine and become an auxiliary motor driven unit along with the water circulating pumps. Sight feed lubricators supply clean oil to the top cylinders and piston rod packings.

Ignition.—The electric ignition is in duplicate. Low tension magnetos with high tension coils, connected to each, supply the necessary current. The left-hand magnetos supply the left-hand ignition plugs in each cylinder respectively, and change-over switches on the coils allow of battery ignition being used as a standby.

Starting Gear. — Compressed air is used in the bottom cylinders only for starting the engine, suitable timing, stop and check valves being employed for this purpose, so that no hand movement of cams is necessary when starting the engine.

FORCING HOME A PISTON HEAD

A nut that came off inside the cylinder brought us the job of making a new rod and piston. We made a splendid fit of these but we had no good way of getting the head clear up to the shoulder on the rod. There was no press within fifty miles and we knew that we would injure something if we used the 24-lb. sledge as a "persuader."

Finally we jarred the head on. It was already within an inch of the shoulder and we turned the assembly, head in the air, resting the cross head end of the rod on a piece of 3″ x 12″ maple plank. A length of rope to the roof truss prevented it from toppling and acted as a safety. A foot of 4″ pipe secured to the plank guided the lower end. Then four good men lifted the job about 6″ at a time and let it drop, soon getting the desired position with this 200-lb. head.

Finding the Easiest Way

ALTHOUGH we have on occasion specifically stated that we cannot furnish actual examination questions and answers, and that we would not if we could, we still receive letters from correspondents requesting just this very thing. Therefore it seems incumbent upon us to once more state our position in this matter.

Power House is a paper for stationery engineers, and as such is willing at all times to help out engineers who have definite problems of a technical or practical nature arising in their daily work. There is one department of the paper open for this purpose under the heading of "Our Question Box" and there is no restriction on the type of question that may be asked, and every effort will be made to provide a correct answer. There is also the "Course of Instruction" which has been running for some time, and it is definitely designed to help engineers who are about to sit for examination. It gives this help by teaching the principles of the subjects that will form the examination, and not by attempting to give specific answers to specific questions. The columns of the paper are always open for correspondence between engineers who have different points of view on any question. When it comes to a matter of procuring the questions that the examination board use in their work, and furnishing these and the necessary answers to candidates who are too lazy to get sufficiently acquainted with their business, and at the same time wish to take a dishonorable advantage of those who have worked and studied to fit themselves for examination we draw the line.

We think perhaps it would be a good thing to forward the next request of this kind that we receive to the examining board, so that they could be on the look out when the seeker after knowledge came up before them. They could then make very sure that the candidate did not have the answers to the questions that were asked. Once more we ask, what good would it do a man to pass an examination in that way, and know himself for ever after as the worst type of what is called colloquially a "four flusher?"

What Are Long Hours?

AT the present time when it seems to be the general aim to reduce working hours to the last possible minimum, consistent with doing any work at all, we often wonder what the power plant engineer thinks of it all. The average man in charge of a power plant works longer hours than probably any man outside of a power plant thinks about, and as a general rule he does it without complaint, and with a ready cheerful spirit. On holidays, a good many Sundays, and Saturday afternoons, when every one else is away, the power plant engineer must be on the job, so that the factory can start up on time to allow the working men to get in their 44 hours or 48 hours as the case may be. If it is a small factory and a small plant where perhaps only one engineer is employed, his hours are bounded usually by his capacity for going without sleep. He keeps the plant going during the day, looks around after the plant shuts down to several little jobs about the boiler room, engine room and factory that must be attended to right away, and leaves off not at any particular hour, but when the jobs are all done. Saturday afternoon and Sunday he devotes to major repairs, and odd little jobs like washing out the boiler, etc. The rest of the time is his own. We remember a case where a long suffering engineer got a job in a hospital. As usual with hospital jobs, the hours were long, and the pay was slightly less than the usual rate, but our friend recognized that times were a bit dull and therefore contented himself, and labored long and faithfully to make the plant as good as possible. One night after he had put in a particularly hard spell for the previous fourteen hours, he had his clothes changed and was all ready to leave for home, when his phone bell rang. Answering the call a polite voice requested him to kindly step up and give them a hand to carry out a body, the orderly who usually helped in this being away. The long-suffering engineer answered this request by the statement that for the future he would be away too, and went sadly away to find a job where removing corpses was not included in the daily routine.

This of course is perhaps an extreme case, and generally the tendency is to make the power plant engineer's working time more reasonable than it was, but still we do not seem to have heard any outcry from engineers for the unreasonable things some tradesmen seem to be after. The stationary engineer as a rule has enough interest in his job and his own reputation to make him willing to give a few hours' extra work without making much fuss about it.

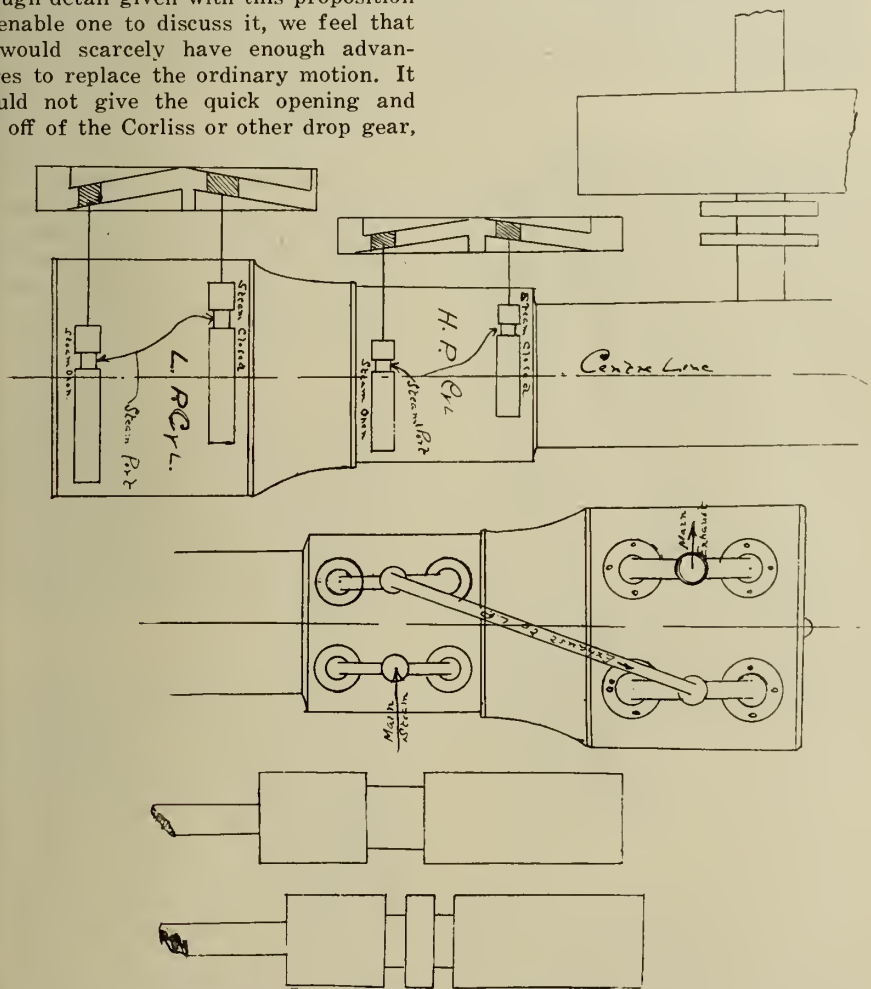
The Operators' Point of View

A NEW VALVE AND MOTION

The sketches here shown have been submitted by a reader of Power House who has a number of original ideas to his credit. While there is scarcely enough detail given with this proposition to enable one to discuss it, we feel that it would scarcely have enough advantages to replace the ordinary motion. It would not give the quick opening and cut off of the Corliss or other drop gear, and as against the ordinary slide valve it would have more moving parts and more sliding friction as compared to the rolling friction of the ordinary valve.



UPPER VIEW—ARRANGEMENT OF VALVES AND MOTION. LOWER VIEW—SINGLE AND DOUBLE PORTED VALVES.

Mr. Walsh, the originator of the gear, is chief engineer of the Dominion Coal Co. at Port au Port, Newfoundland, and the following is his own description of his idea: "You will note that this valve and motion is of the sliding type, thus doing away with the half rotary and wrist pin motion. The H.P. admission motion is worked from a fly wheel governor to give early cut off under light loads. The motion is carried on a table or carriage, which has a channel cut in it. The wedges or inclines are fitted in this table, and adjustment made by set screws. The carriage itself travels in a V-shaped groove similar to the bed of a lathe or planer. The valve shown is a single ported valve, with exhaust arranged to take place between the end of valve and the cover. There is a steam tight collar on front end which is meant to reduce the pressure on packing. The valve spindle is made heavy on account of the bending motion due to the side travel of block. The spindle is connected with a toggle block. When the motion moves the block travels path of incline, thus moving spindle in or out. I think the device would make a very positive action. You will note that each cylinder has two valves and each valve has its own steam and exhaust independent of the other valve. Thus each valve attends to work of piston for the full length of stroke."

SOME MORE COMMENT

In the Power House of March 5th you ask for some comment from your readers on the perpetual motion compressor described by H. Nicholaides in that issue.

According to Mr. Nicholaides he has had technical men reviewing his discovery, and has obtained an "action" from the Patent Office, whatever that might be.

Being a youngster in the engineering profession, the writer would like to see this mysterious machine which shows an efficiency of over 100 per cent. "shown up."

It is contrary to the teaching we are getting from our tutors and text books.

No doubt there will be lots of comment on the Californian's article by technical men, but we will try and let you have a fourth class steam engineer's view of it.

In the first place let us consider a well-known cylinder used for compressing air, a common automobile tire pump.

By depressing the handle and incidentally the leather washer or piston, the air at atmospheric pressure below the piston is reduced in volume, and according to Boyle's Law, which our friend has frequent recourse to, the pressure in the cylinder is raised inversely as the volume.

This can be sensed by the increasing force required to depress the handle as the stroke continues.

At ¼ stroke the pressure in the cylinder will be raised inversely as the volume and become 15 lbs. (atmos.) times 4-3, the latter figure being 3-4 inverted, this is equal to 20 lbs. absolute, which is 5 lbs. above atmospheric.

At half stroke the pressure will be 15 lbs. and so on until the tire pressure is reached when the pressure on both sides of the tire valve is balanced. Then by still depressing the handle the pressure is raised enough to overcome the valve spring and the charge of compressed air enters the tire.

Although the pressure, when the valve opens, it, let us say, 70 lbs. per sq. in., the average pressure on the piston may

not have been higher than 25 lbs. per sq. in.

Supposing the pump cylinder to be 1 sq. in. area and the stroke one foot, then the work done would be around 25 ft. lbs., and not 70 ft. lbs., as Mr. Nicholaides would no doubt figure.

From the foregoing we can see that the same results can be had with one cylinder of 8 ft. stroke as with a fantastic battery of 8 cylinders, each having a stroke of one foot.

In figure 1 is shown a steam cylinder B, and an air cylinder A, directly connected. Just as soon as the piston is caused to move downwards the air in A is reduced in volume, and its pressure is therefore increased, so that some force is required to overcome this increase in pressure.

Both pistons are assumed to have an area of one sq. ft., so an increase of 1 lb. for sq. in. of air in A will need a similar increase of steam pressure in B to effect the continuation of the stroke. All of this is neglecting friction, of course.

As the pistons descend the pressure in the air cylinder increases until the point e is reached, which is 10-11 of stroke theoretically. At this point the air is reduced to 1-11 of its original volume, and in accordance with Boyle's Law again, we get an absolute pressure of 15 x 11 = 165 lbs. per sq. in., or 165 — 15 = 150 lbs. per sq. in gauge pressure, which is, roughly speaking, 10 atmos.

At this pressure the discharge valve opens to the receiver, the pistons complete the stroke and "the cubic foot of air is found compressed to atmosphere in the reservoir!"

Figure II is a theoretical diagram of what takes place in the air cylinder. XY is zero, and AB represents atmospheric pressure. (In this case 15 lbs.)

The stroke commences at (a) and as the piston descends the pressure is indicated by the curve until (e) is reached when the pressure is 150 lbs., and remains so until the end of the stroke (b).

The average height of the pressure line can be found by dividing the area of the figure a e_1 b_1 b e by the length a b.

From this we get the mean effective pressure on the air piston, which is, roughly, around 35 lbs. per sq. in.

The average total pressure on piston times the stroke in feet gives us the work done per stroke, in this case, 35 x 144 x 1 = 5,040 ft. lbs.

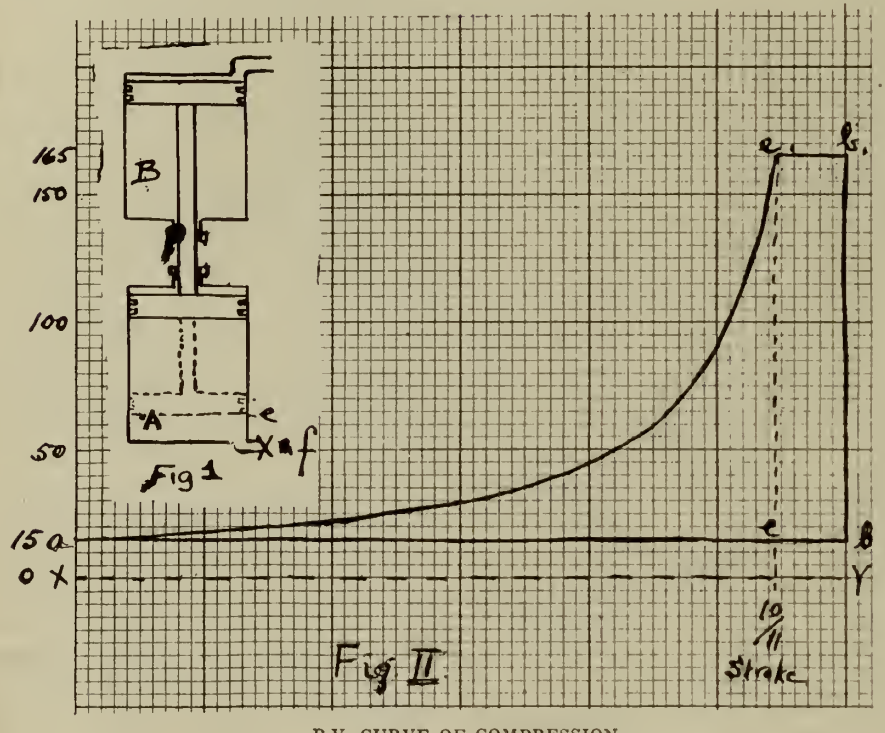
The work done in eight such strokes = 5,040 x 8 = 40,320 ft. lbs., and not 172,800 ft. lbs., as Mr. Nicholaides would have us think.

Presumably he imagines that 150 lbs. per sq. in pressure is required on the steam piston during the whole of the stroke. Nothing is more absurd.

As a matter of fact, with steam at 150 lbs. and counting all losses an engine cutting-off at 1-3 stroke would drive the air piston comfortably.

Our friend by frequently employing his "scientific calculations" finds the ultimate total pressure on a bunch of pistons, adds them together and calls the sum the amount of work in foot pounds done in the cylinders.

I hope I have not trespassed on your time unduly, Mr. Editor, and hope to read more able comment from other contributors.



P.V. CURVE OF COMPRESSION

ANNOUNCEMENT

The sales management for Riley Underfeed Stokers and Murphy Furnaces has been concentrated under one head William Pestell, formerly Western sales manager with headquarters at Chicago now becomes sales manager with headquarters at 1226 Woolworth Building New York city. W. L. Bigelow becomes district manager of the Pittsburgh territory, while C. Lincoln Smith goes to Cincinnati in the same capacity.

To better serve the territory in and around Kansas City, the F. M. Beeson Machinery Co., 308 Mutual Building Kansas City, Mo., have been appointed sales agents for both Riley Stokers and Murphy Furnaces.

Sales in Denver territory will be handled by Stearns-Roger Mfg. Co., 1718 California Street, Denver, Col.

The Boston, Buffalo, Cleveland, Detroit, Chicago and St. Paul offices remain as heretofore.

The Homestead Valve Manufacturing Co., Inc., have made some additions to their New York sales force. Mr. N. A. Althouse and Mr. E. V. Curran have joined the staff and will be attached to the office at 242 Lafayette Street, New York City.

We have received the booklet just issued by the Allen General Supplies, Limited, Toronto, describing the various lines handled by this firm. This includes water softening and filtration plants, boiler feed regulators and pump governors, Venturi meters, feed water heaters, etc. The various lines are well illustrated and described.

We have received from the H.S.B.W. Cochrane Corporation, Philadelphia, a very useful book on boiler room problems. The volume is entitled, "Finding and Stopping Boiler Room Wastes," and contains over 400 pages. The contents include Fuels, Combustion, Boiler Efficiency, Heat Absorption, etc., and all these subjects are treated very fully and are very well illustrated. The book has been compiled and edited by George H. Gibson and is published at $1. It is bound in cloth covers, and is well worth a place in the office of any chief engineer or power plant superintendent who requires a book for ready reference on any of the subjects included.

The successful contestant this year for the gold-headed cane annually presented by the Montreal Harbor Commissioners to the captain of an ocean liner first bringing his ship to the port goes to Captain Michael Doyle, of the Cunard freighter Venusia, which arrived last Thursday night from London.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

CAPACITY OF AIR COMPRESSOR

Question:—How do you figure the capacity of an air compressor marked 12 x 12, speed 200 r.p.m., air pressure 100 pounds per square inch?

(2) What percentage of ash should there be in coal?

(3) Would you divide ash by coal or coal by ash?

Answer:—The capacity of an air compressor is calculated in cubic feet of free air per minute. If the cylinder is 12 inches diameter by 12 inches stroke, each stroke draws in a volume of air $1 \times 1 \times .7854 \times 1$ or .7854 cubic feet. If the compressor is double acting the piston displacement per minute will be $.7854 \times 400 = 314.16$ cubic feet, and this is the amount of free air the machine would handle, neglecting losses.

The percentage of ash in coal varies very widely from 5 per cent. in the best bituminous or semi-bituminous steam coal, to as high as 20 per cent. or 25 per cent. in some grades of anthracite.

The percentage is found by dividing the weight of coal into the weight of ash and multiplying by 100. For instance, if we have 2,000 pounds of combined coal and ash and 400 pounds of it is ash the percentage would be $400 \div 2{,}000 \times 100 = 20$ per cent.

QUESTION ON LOAD FACTOR

Question.—In reading a recent issue of the Power House I was much interested in the article, Effect of Load Factor on Station Cost. However, I did not fully understand your explanation of the term "Load Factor," as I have been instructed the way to determine the load factor of a power unit is the ratio of the full capacity of unit to the indicated load, i.e.: If capacity of unit is 500 kws. and indicated load is 100 kws., then l.f. would be 20 per cent., and to get average l.f. take ratio of capacity of unit to the average No. of kws. for any given period, i.e., average No. of kws. for 24 hrs. = 50 kws., then average l.f. would be 10 per cent., also to get maximum l.f. with capacity of unit at 500 kws. and maximum load 300 kws., then maximum l.f. would be 60 per cent.

Would appreciate the favor very much if you would kindly let me know if I am in error and explain proper method giving an example in figures.

Answer.—If you were discussing load factor as related to the output of a machine as compared to its full capacity (rated) the method you describe would be quite correct. However, as explained by the author of the article in question, load factor as used to determine capital charges on an investment is the number of kilowatt hours of output as compared to the possible number of kilowatt hours based on an average demand. For instance, in Fig. 4 of the article in question, the chart for Monday shows practically no load from midnight till about 6 in the morning. The load then jumps to 10,000 kw. till noon, when it drops again till just after one o'clock, and drops again from 6 till midnight. If the demand be taken as an average of 10,000 kw. during the normal working period, then the total possible output would have been 10,000 x 24, or 240,000 kw. hours. Actually the output is only a little over half of that, or 54 per cent. as shown by the chart. Now take on the holiday the demand on that day is low, but the curve is very flat, that is the average load or output approximates fairly closely to the maximum. Thus the load factor on that day is higher than on the working day. If the load factor was based on the capacity of the station it would have the effect of making the load factor very low on holidays and Sundays, while in this case it is just the opposite.

A PECULIAR ACCIDENT

A rather unusual accident is reported in a contemporary as having occurred to a turbo blower set. It having become necessary to change over from one set to another, the engineer in charge signalled to his assistant to shut down the first machine as the other took the load. This was done, but the assistant neglected to close the valve in the blower discharge, with the result that the air pressure in the main drove the closed down set in the opposite direction. The lubricating arrangement which would only operate in the natural direction, failed to give any oil to the bearings and in a short time they warmed up and seized.

BOOK REVIEW

We have received a copy of a book issued by the De Laval Steam Turbine Co., Trenton, N.J., entitled "Ten Years' Progress in Water Works Pumps," dealing chiefly with the development of pumping station units. The opening pages of the book are devoted to a discussion of the economies of different types of pumping engines, and are divided under headings including "Adaptability," "Duties Developed," "Pumping Costs" and "Capital Charges," and these subjects are illustrated by curves. There are also curves showing cost of steam under different conditions. A long list of municipalities which have adopted the De Laval centrifugal pumps follows, and a large number of installations are illustrated. A most interesting portion of the book is that dealing with the testing of steam turbines and centrifugal pumps and the methods of measuring head and discharge capacity. Some interesting data on orifices and nozzles are included. In compiling this data the author has made a very exhaustive search through all the literature published in English, German and French, and is probably the most complete ever assembled in this form. The book is handsomely turned out and should be of great value to any engineer interested in these problems.

The Crane Packing Co., 1800 Cuyler Avenue, Chicago, U.S., have published a book on "Metallic Packing" dealing with its development uses and correct application to modern equipment. While the book is frankly a catalogue of John Crane packings, it is also full of useful information on a subject which is very interesting to every engineer. Practically every form of service to which packing can be put is treated, and a number of interesting illustrations are included.

The Dominion Steel Products Co., Ltd., of Brantford, announce that they have taken over the sole agency in Canada for the Darling (patented) compression hydrant, and these hydrants will be manufactured at their plant in Brantford. The Darling hydrants are manufactured in the United States by the Darling Valve & Mfg. Co., where they also make the Darling (patented) gate valve. This valve, as well as the hydrant, will be in future manufactured for the Canadian trade in Brantford.

Telling The Story of Oil*

THE throne of King Coal in the world of industry and commerce is rapidly being usurped by his royal brother, King Petroleum. Royalty is becoming scarce in the regeneration of nations, and these royalties are not an exception, though to retain them is the earnest desire of everyone. Commerce depends upon transportation and industry, and both of these depend upon fuel. Never has there been such a demand for oil. With the derivatives of petroleum we run our airplanes, automobiles, motor trucks, and with it as a direct fuel we are beginning to furnish steamships, railroads and factories with the power to keep them at work.

This huge demand for oil has drawn greatly on the natural resources of the earth's limited supply. It is estimated that in 1921 there will be twelve million automobiles in the United States, requiring 430,000,000 barrels of petroleum to hold the fuel gasoline at a fair proportion to supply the demand. Since 1911 the number of automobiles has increased ten times, while the increase of oil production in this country has increased but one and two-thirds times. The increase in cars for 1920 equals 32 per cent. over 1919, while the oil increase is but seven per cent. Comparing the demand for oil during a four months' period of 1920 with the available supply for the same period, it is found that there is a draw upon our surplus equivalent to a deficiency of a 56-day supply. It can easily be seen that something must be speedily done to combat these conditions. New oil wells must be opened and new methods must be discovered to attain greater efficiency in getting the oil from the earth, as well as more economic conditions of refinement. It is stated that only about twenty per cent. of the oil is taken from the ground in any well; eighty per cent. is left in the ground because we are unable to get it out. This is the problem for engineers to solve.

There are two widely differing opinions as to how the oil originated in the surface of our planet. Chemists have been able to make many of the derivatives of petroleum in the laboratory by following the principles of what is known as the "chemical theory" of the origin of petroleum. Under heat and pressure the chemical compounds of hydrogen and carbon have produced some of the by-products which can be obtained from crude petroleum, but on a commercial scale the process involves too great expense to be of economic value at present. When all the oil has been taken from the ground, then perhaps some method of synthetically making the necessary by-products of petroleum will be found.

The second theory, that held by geologists, is that petroleum was formed in the rock in a manner somewhat similar to the formation of coal. From organic bodies, both plant and animal, living in the remote past came the various grades of oil found in broadly scattered areas of the earth. The heat energy of decaying vegetable matter, as well as that of animal organisms, was preserved in the sealed pressure-chambers of the rock. This stored-up energy of the early days of life on the earth now furnishes the fuel for factory and steamship, airplane and automobile. Whether of inorganic or organic origin, Father Time hoarded the treasure of oil in his vaults beneath the ground, and to-day we are taking out the treasure without the means of replenishing the supply.

A modern oil refinery is one of the most interesting places for a layman to visit. If he intends making a thorough inspection of the industry, he really ought to begin his journey at the wells. The United States is the greatest source of oil in the world at present, though Russia promises to again take the lead. Mexico, the East Indies, China, South America and other countries also contribute to the world's supply. The petroleum from different localities differs widely in quality, and often there occurs a variation in exceedingly narrow limits of territory. Indeed, the grade of oil from a single well may change its character to a surprising extent. The methods of purifying or refining all these varieties of crude oil must necessarily differ in details, and the general plan of refining the crude petroleum serves merely as an outline of the many processes. Only the common skeleton will be described here, and the methods used in one refinery will often be found considerably modified compared with the conditions of another.

When the first oil wells were drilled in this country the manner of conveying the oil to the places best adapted for its refining was a great problem. It was hauled in barrels in carts, transported in tank cars, and finally piped from the well to the refinery. Thousands of miles of pipes now connect the oil wells with the localities best adapted to treat the oil and remove its impurities, its bad odor, and reduce it to the various factors required in its widely differing uses. From the oil must be taken gasoline to run automobiles; kerosene to be used in lamps and heaters, and for operating certain types of internal combustion engines, and finally what is known as "paraffin distillate," from which lubricating oils are obtained.

There are distinct processes of refinement. Each depends upon the amount of a certain product to be obtained as well as upon its desired quality. The crude oil is subjected to gradual heating, and the vapors given off under the distinct variations of increasing temperature are condensed and further refined. This process is technically known as fractionization. Crude petroleum heated in a crude still first gives off its lighter oils, those which evaporate at low temperature. Like water, oil evaporates slowly when exposed to the air, the more volatile substances of which it is compounded being easily lost. As the temperature is raised, heavier substances are turned into vapor, and so on, until finally only coke remains as a residue in the bottom of the still. It can easily be seen that when heat is applied to a still containing crude oil, not only its lightest vapors immediately are given off, but some of those farther down the scale of weight, or specific gravity, manage to escape with the lightest ingredients. This necessitates further distilling the lighter oils, until finally the heavier substances which have escaped with them are collected. It is unnecessary to say how important is the use of temperature measurement in the distillation of the petroleum. Not only must the color of the oil be watched at the still to indicate the grade of oil that is coming off, but the most precise observation of the temperature of the fires under the still must be observed. Tycos still thermometers figure prominently in the whole of the refining processes. In fact, they find a place along the pipe lines, because the temperature of the oil while being piped to the still is necessarily observed at certain pumping stations during the changing seasons of the year.

After the various "fractions" of the crude oil have been obtained, the refined oil distillate, the naphtha, and the paraffin distillate receive chemical treatment to remove impurities, the sulphur, and to improve the color and odor of the oils. This chemical treatment consists first in agitating the oil with sulphuric acid. After this agitation there settles in the bottom of the oil a heavy mixture, the tar-like material which was held in suspension. This material is further treated and separated into three layers. The top layer consists of acid oil, the next layer of acid tar, and a layer of weak acid at the bottom. The middle layer of acid tar may be used for its asphalts or burned as fuel. After this treatment the

oil is further purified by filtering it through clay.

So much for a brief outline of some of the fractionization methods employed in the oil industry. What is known as "cracking," a process which actually splits or cracks the molecules of the oil by means of intense temperatures under pressure, refinement to produce materials of certain quantity and quality are obtained. It is estimated that refiners can get two times the amount of gasoline from crude oil by the new cracking methods employed, giving 35 per cent. compared with 12 to 22 per cent. obtained by old methods. In this process the matter of exact temperature control, as well as pressure regulation, is of vital importance. Raise the temperature in a still to a high degree and the heavier substances as well as the lighter are turned into vapors which can be condensed into the derivative desired. The processes, however, vary widely according to the kind of oil that is handled, and each is calculated to suit the particular grade of substance with which it must deal. The crude oil produced in this country is a fair representation of the world's petroleum; it contains spirits, oils and solids. After being filtered through animal charcoal to remove mineral particles held in suspension, the oil is sent to the stills, which may be worked in batteries of three or more, each handling 24,000 gallons.

Fractionization, in which the volatile spirits are removed by a temperature between 100 and 125 degrees F., and followed by taking out the light oils at a temperature between 215 and 230 degrees F., producing kerosene and paraffin, is usually first employed. Further heating causes the heavy oils to come off. These, redistilled under a pressure of 250 pounds to the square inch, start the "cracking" process.

Water, at atmospheric pressure, boils at 212 degrees F., but if it is placed in a closed container and the surrounding pressure is raised to 150 pounds a square inch, then the temperature must be raised to about 366 degrees F. to make the water boil. The boiling point of a liquid is merely the temperature at which its vapor pressure equalizes the external pressure upon the liquid. The comparison applies to oil. With a high pressure it is possible to obtain the high temperature necessary for rapid cracking, preventing at the same time much of the lighter substances from distilling over. When a temperature of 700 to 725 degrees F. is reached the rate of cracking becomes very rapid, and here the pressure still is required.

Tycos thermometers as well as pressure gauges are dependable throughout the process. In the first treatment where fractionization is employed the thermometers enable precise observation of how great or how little heat is to be used under the stills. Each precaution must be taken in cracking for kerosene. The product obtained as the next heavier grade from naphtha receives chemical treatment and is then removed to be redistilled in the fire and steam stills. While gasoline is obtained from the lighter naphtha, kerosene is obtained from this second heavier product. The oil to produce kerosene is fed from one still to another in a series, each employing a successively high temperature. Heat is applied by fire and continuous sprays of steam, the free steam passing up through the oil carrying off the oil vapors from the top of the still where they are condensed.

In the case of gasoline, steam is alone used for heating, the danger of combustion being too great when fire is applied under the stills containing the highly combustible naphtha. Here also free steam is sprayed to carry off the oils up through a tower where they are cleansed.

Without precise temperature measurement the oil industry as it exists today would not be possible. There would be so much waste in lost derivatives that only a small proportion of the much needed gasoline, kerosene and lubricating oils could be obtained. We would thus lose what little we have, and there would have been such a handicap in the matter of fuel that the automotive industries would surely never have reached their present important place in our affairs. It is a matter now of taking advantage of the utmost economy in fuel production. There are new methods and improvements being discovered, and these are made possible with the aid of the thermometer. They will prolong the day of the gas engine, and perhaps save us from an oil-dry planet.—Tycos-Rochester.

MAKING BOLTS FIT TIGHT

In connection with some work on American battleships, a report of the Bureau of Standards says it was found necessary to use bolts capable of withstanding unusually high shearing stresses. The best type of bolt for such purposes is one having a tight bearing over its entire length. The bureau was requested to devise a method by which such tight-fitting or "body-bound" bolts could be secured. Two methods were tried, both of which gave satisfactory results.

In the first case the bolts were finished a little larger than the holes in the plates. They were then immersed in liquid air until they contracted sufficiently to enter the holes quite easily. Upon warming up, the bolts expanded, gripping the plates tightly. In the second method each bolt was provided with a small hole along its axis and was finished to be an easy fit in the plates.

After insertion a charge of powder was exploded in the small hole. This expanded the bolt, causing it to grip the plates. Subsequent physical tests indicated that the strengths of the joints secured by both methods were sufficiently high for the purpose.

PROVINCE BUILDS CEMENT PLANT

Believes It Can Turn Out the Required Supply at Price Below Market

The Ontario Legislature in committee of supply on the estimates approved of a vote of $1,000,000 for the carrying out of Hon. F. C. Biggs' scheme to establish a provincial cement plant. The Minister explained that the amount voted would build a one-unit plant with a capacity of something over 300,000 barrels annually, which would be sufficient to supply the needs of the province for its provincial highway program. He stated the location of the plant had not been decided upon, but that the department was negotiating for options on alternative sites. It was expected that the province would be able to produce cement at prices much below those prevailing, and moreover would be assured of an adequate supply instead of having its work held up by difficulty in getting delivery.

AN ADAPTABLE WRENCH

The Universal Wrench Co., Detroit, Mich., have opened a factory and office in Windsor, where they will manufacture their universal adjustable wrench. This wrench differs from the usual type of adjustable wrench by the addition of a lever mechanism which permits of pressure being applied to the jaws. A heavy duty spring opens the jaws to the determined position, when the lever is released. Among other advantages claimed is the non-slip feature—as it is said that the wrench cannot slip off the nut. It is also adaptable to smaller space as the handle need not be swung from flat to flat, but only far enough to permit the grooved jaw to grip on the nut angle. These wrenches are made of special material and are turned out in sizes from 4 to 18 inches.

ANNOUNCEMENTS

The Chicago office of the Uehling Instrument Co., of New York, manufacturers of fuel saving equipment, was moved May 1st to the Great Northern Building, 20 West Jackson Boulevard. Mr. Walter C. Lange, who has been appointed manager of this office, is particularly well qualified to co-operate with power plant operators in solving problems of fuel conservation because of his former experience in this field with the Consolidated Gas Co., of New York, and the Hammel Oil Burning Equipment Co., and, until recently, in the New York office of the Uehling Instrument Co. Mr. Lange is a member of the American Society of Mechanical Engineers and a graduate in mechanical engineering of the Stevens Institute of Technology. Uehling Co. recording equipment and other boiler room instruments will be on display in the new office.

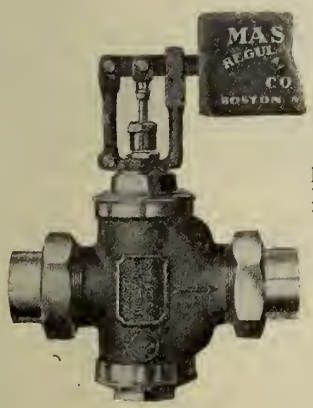
Where You Buy Principles!

DID you ever consider that "principles" are the thing to buy when choosing Valves, Steam Traps or Regulating Appliances. Far greater than mere claims—of more consequence than outward appearance—are the principles that shape a manufacturer's policy.

When you buy Mason Appliances you also get "principles." Principles that allow nothing to interfere with the high standards of Mason efficiency. You buy these principles and yet they cost you nothing.

New Bundy Return Steam Trap

Mason Standard Bronze Reducing Valve



Mason Balanced Valve

MASON EQUIPMENT

is the result of over forty years' manufacturing experience. Service, reliability and positive action is built into Every Mason Appliance.

At your service, in your choice of Mason Devices, is a staff of competent Engineers. Their job is to see you don't waste money on the wrong type of equipment.

The 2-part TRAP—individually tested

When the Testing Stand at the factory puts the O.K. on a trap, that trap is ready for business. Installed on a radiator, it will stop the steam and pass the air and water. It will keep on doing this for—well, we don't know for how many years.

Many of the original traps after seventeen years of continuous service are still operating satisfactorily and with promise of working indefinitely.

Mechanically, the Dunham Trap is better today than it ever was. The principle of operation is the same today as when the trap entered the Patent Office. Of this fact, we are rather proud. To you, it will perhaps indicate that Dunham Standards are stable, and of known value, and can be depended upon to serve you.

We believe that you can profitably co-operate with Dunham Service. May we explain?

Dunham Specialties

Extravagance Must Stop!

THE COPES Boiler Feed REGULATOR

is a vital organ in the system which draws the latent energy out of the coal pile and delivers it at the bus bar or the main drive shaft.

Without the Copes Boiler Feed Regulator none of the other organs can perform its function properly. Stokers, feed water heaters, water softeners, and the boilers themselves cannot do their best without proper feed water regulation. The legibility of steam and water flow records, pressure and temperature charts, all depend more or less on scientific feed water regulation.

For complete information about COPES BOILER FEED REGULATORS, ask for Bulletin D.

CHANGE OF ADDRESS

A REQUEST FOR CHANGE OF ADDRESS must reach us at least thirty days before the date of the issue with which it is to take effect. Duplicate copies cannot be sent to replace those undelivered through failure to send this advance notice. Be sure to give your old address as well as the new one.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

EQUIPMENT

For Sale

A number of 100, 150, 200 and 300 H.P. engines of massive construction, ex tanks, etc., not aero engines, absolutely brand new, in crates suitable for tractors, small vessels, pumps, lighting, winding engines, driving auxiliary machinery, etc. These engines are complete and were built for heavy duty Government use by Daimlers, Gardners, Hornsby, Brotherhood, etc. Prices from £200 F.O.B. English port. Spares for all parts in stock. These engines must be sold and a large reduction would be made for quantities. Cable for particulars.

Tom Taylor

Marine Engineer, Staines, England

STEAM ENGINES, BOILERS, HEATERS, tanks, stacks, pumps and condensers, transmission and elevating machinery, safes, vaults and vault doors; catalogue and specifications sent on request. Apply, mentioning "Power House," to Goldie & McCulloch Co., Ltd., Galt, Ont. (pfh)

PORTABLE BOILERS—LOCOMOTIVE TYPE, on wheels, each 15 horsepower, with engines mounted on boilers; can get Government certificates for 90 and 100 pounds working pressure; cheap; also 40 horsepower, high speed Leonard automatic engine. Apply, mentioning "Power House," to Henry Engineering Co., 71 Bay Street. Toronto. (pfh)

BOILERS AND POWER PLANT EQUIPMENT bought by the Henry Engineering Company (Henry-Rumgay-McBryde), 71 Bay St., Toronto. Mention "Power House." (pfh)

BELTING

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto. (p.f.h.)

MACHINERY WANTED

EQUIPMENT WANTED — 550 H.P. CORLISS type steam engine; 250 H.P. Corliss type steam engine; 36 or 42 Corliss iron planer; wood turning lathe pattern maker's type (all iron); boilers, small and large. The Andrew S. Forman Co., Reg., Room No. 60, 232 St. James St., Montreal, Que.

NON-CORROSIVE

CYLINDER OIL

MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

EMPLOYMENT DESIRED

POSITION WANTED BY AN EXPERIENCED refrigerator engineer, also competent in ice making and electricity. Address, D. M. J., Power House, Toronto. (pIh)204

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers, Corliss and all classes of stationary engines, compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St., Toronto. (pfh)

MACHINIST—WITH DRAUGHTING EXPERIence, wants work of any kind. N. Ryckman, No. 174372, 5 Foxley St., Toronto. Phone Parkdale 3254w. Mention "Power House." (pfh)

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House. (pfh)

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House." (p.f.h.)

WHEN WRITING TO ADVERTISERS PLEASE MENTION THIS PAPER

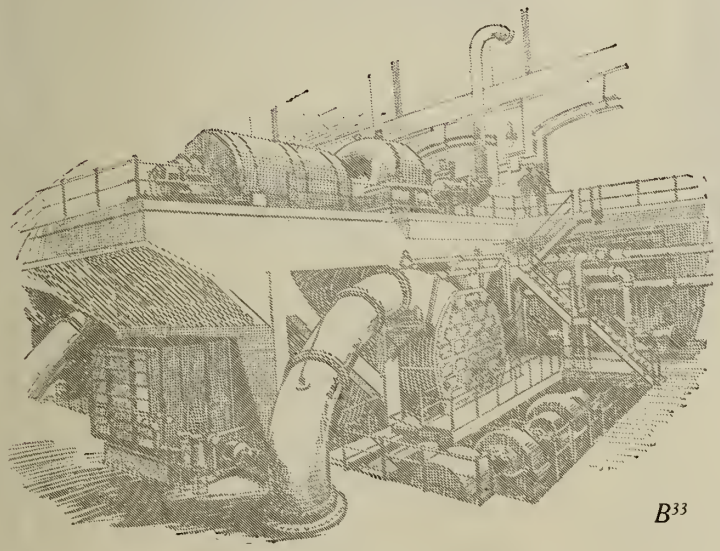
Proficiency in pumping is as necessary as completeness of combustion

WHEN dense smoke pours from the industrial stack, something is done about it. Those bits of wasted fuel must be reclaimed; and their mite of heat must be extracted on their way through the combustion chamber. Heat waste is inexcusable.

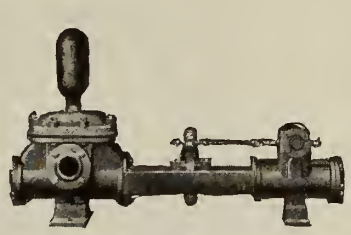
And equally inexcusable is the waste of energy in pumping operations. For there is a Worthington machine for every pumping operation which will do the work at top economy; and the Worthington Pump and Machinery Corporation maintains a corps of engineers whose chief duty is to advise on the selection of the right machine for every task.

The use of any but the *right* unit on any pumping or condensing installation is wasteful. And hundreds of such problems of pumping ineffectiveness have been solved by putting it up to Worthington. There's a Worthington solution for every pumping problem.

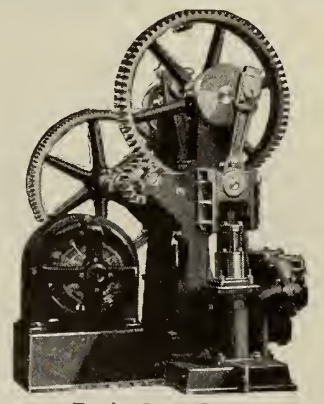
WORTHINGTON PUMP AND MACHINERY CORPORATION
Executive Offices: 115 Broadway, New York City
Branch Offices in 24 Large Cities



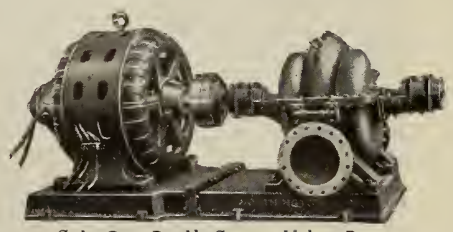
B33



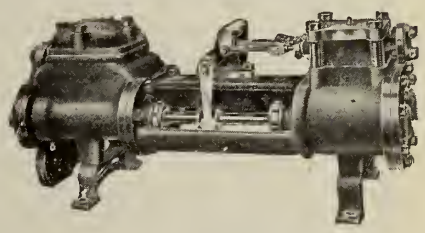
Simplex Direct Acting Steam Pump



Triplex Power Pump



Split Case Double Suction Volute Pump



Duplex Packed Piston Pump

The most popular, all-service pump built. The sale of this pump has reached such proportions that Worthington has been enabled to so refine manufacturing that the pump purchaser gets for his money the largest possible value. Proven design plus first quality materials guarantees maximum pump utility—most pump per dollar, most duties per pump.

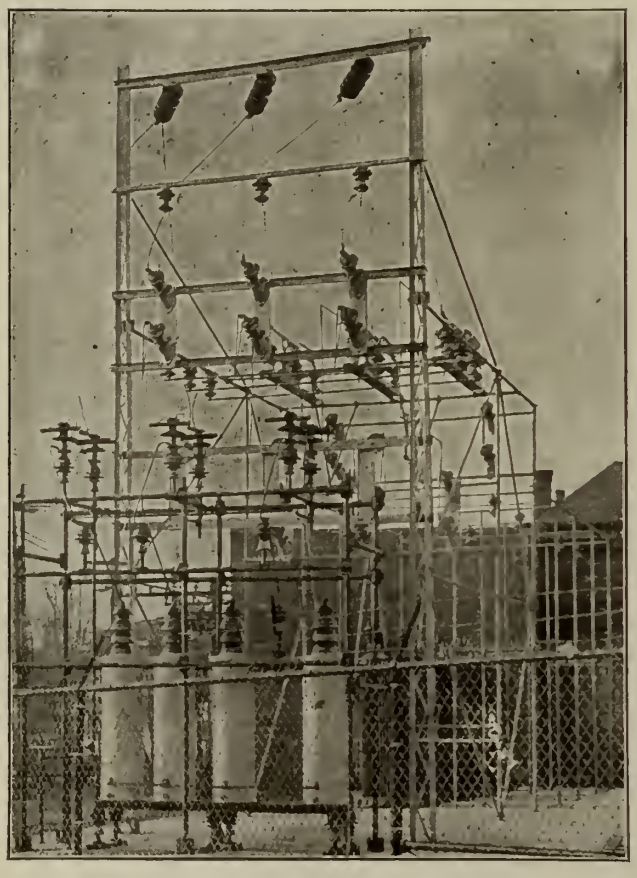
PROTECTIVE DEVICES



A typical Outdoor Sub-station, embodying Electrical Engineers Equipment Company Protective Devices

Exclusive "Three E" Features

Discharge Gap Lightning Arresters are essentially high speed with large capacity spheres having a ground resistance in series limiting the dynamic current to two amperes or less.

Disconnecting switches have contacts and blades arranged to always insure thorough contact without possibility of loosening after many operations. Simple operating mechanism provides powerful leverage when first breaking contact and greatly increased speed with reduced leverage, later.

Choke coils are well supported by patented Y-shaped clamps on ends and are further braced where necessary.

Our nearest house will give you full data and recommendations on these or any other "Three E" Protective Devices and Switchboard Fittings.

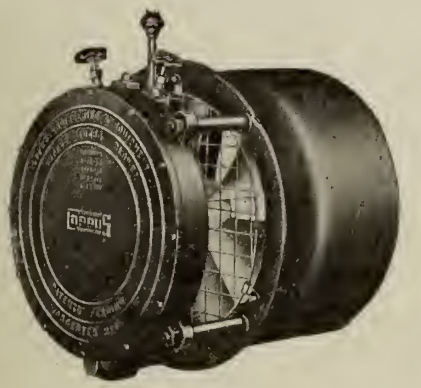
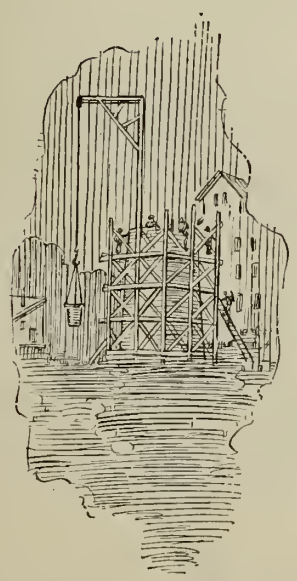
Instead of a new Chimney



REGISTERED COPPUS U.S. PAT. OFFICE

TURBO BLOWER



WHEN the need for greater draft for your boilers arises you naturally think of a new chimney as the logical remedy.

A chimney has serious limitations—it is costly to erect, requires time, and causes many inconveniences around the plant, such as accumulated material, dirt, dust, scaffolding, and no small amount of danger.

Instead of a new chimney, think of the advantage of a Coppus Turbo Blower at only a mere fraction of the cost of a chimney, with far more satisfactory results.

The Coppus Turbo Blower provides abundant draft for any boiler and increases combustion even with the cheapest grades of fuel.

The Coppus overcomes the draft resistance of the fuel bed and the boiler by forcing the air through the fuel bed, leaving to the stack the overcoming of boiler resistance only.

Tests have demonstrated that the Coppus Turbo Blower adds 25 to 100 per cent. to the rated capacity of a boiler, and in connection with mechanical stokers often as much as 200 per cent., saving the installation of new boilers and the necessity of enlarging the plant to accommodate them.

Which is cheaper in the long run, and more satisfactory—a compact, automatic, easily-regulated Coppus Turbo Blower, or an expensive, cumbersome stack, lacking in the results that make for economy in the power plant?

The answer is Coppus, with its Valve Control of Your Steam, economy and better combustion. Therefore, instead of the new chimney, install a Coppus Turbo Blower and get greater economy.

Shall we send you the booklet fully describing their construction, installation and advantages? We shall be glad to do so on your request.

"The Spectre"

By Guy Morton

"LONGREEN was not a quibbler.

"'I am sorry, Grimley' — he came straight to the point—'but we are compelled to dispense with your services at the end of the month. Turner's for the past six months has been having a terrible pull. We got overstocked on the rising market and now, with the market falling every day and getting more and more into the customers' hands, we have to retrench or crash. We have chosen to retrench. Every stick of decorative employment is being cut out of the store. . . .'"

What Spectre? The Spectre of Unemployment—a spectre which all too many have encountered during the past few months. If you have not personally encountered this spectre, so graphically described in its causes and consequences by Guy Morton, you may count yourself amongst the fortunate, but there will be no doubt as to your interest in his story. If you have encountered it, nothing can stop you, once you start this story, from reading it to its unusual and constructive conclusion.

It is a great piece of fiction, told by the same author who wrote "Personality Plus" in the March 15th MacLean's.

"The Drama of Our Great Forests": Life and Love Return— *By Arthur Heming*

This is the seventh installment in Mr. Heming's wonderful account of life in our northern forests and pictures the fascination of real romance in the wilds.

"Have Faith in Our Nationals"— *By Agnes C. Laut*

There is no use always knocking, says Miss Laut. By a constructive policy of immigration and settlement, some of these deficits can be vastly reduced.

"Conversation vs. Closure"— *By J. K. Munro*

Premier Meighen is struggling against great odds to carry through some constructive legislation. According to Mr. Munro, they are really not getting anything done at Ottawa—and he tells how they do it in his masterly, pungent, pithy, witty fashion.

"She Wasn't a 'Type' So She Became a Directress"— *By Edith M. Cuppage*

The story of a B.C. woman who wanted to get into the movies—and got there, despite everything, in the administrative side.

"Heads Million Dollar Corporation"— *By Dorothy G. Bell*

The story of a Canadian girl who went to the States with an idea that she might become a dancer, but has made for herself a niche as head of a million dollar financial corporation.

"Our Own Mediterranean"— *By Elton Johnson*

What's what at the present time in regard to the movement which is on foot to make ocean ports of our Great Lake ports.

"Making Good on Four Ambitions"— *By Sinclair Laird*

The story of W. S. Bullock, a member of the Provincial Legislature of Quebec Province, who did not know his multiplication table at 19 and is now a leading educationalist.

"Pawned"— *By Frank L. Packard*

This masterly story of a triple regeneration is drawing swiftly to its conclusion: John Bruce and Crang meet again at death-grips.

"The Gates of Tien T'ze"— *By Leslie Howard Gordon*

The first "gate" is entitled "The Gate of Wu" and starts off this thrilling, absorbing, melodramatic story with several full pages of gripping adventure.

"The Cage of Iron"— *By William Merriman Rouse*

A story of an old man who thought he could take into his own hands the vengeance which the Creator intended should be left for Himself.

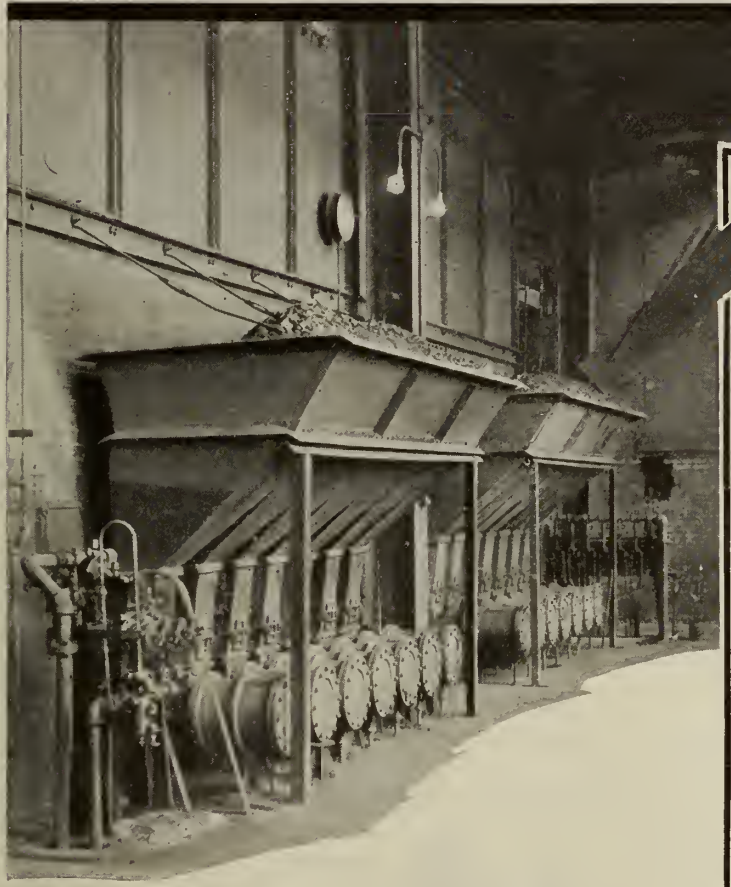
JONES STOKERS



POWER interruptions will not, and should not, be tolerated in modern plants. That is why Jones Stokers are favorites for plants of practically every size. Their rugged simplicity makes shut-downs for repairs next to impossible. Fuel and air are automatically controlled; little attendant labor is required.

In the "A-C" (Automatic-cleaning) type, fires are automatically cleaned.

Retorts may be individually controlled—an exclusive feature.

Clinkers do not form on bridge or side walls.

The under-feed principle of combustion (originated in Jones Stokers) insures maximum economy of fuel at all loads.

These, and other distinctive features that make the Jones Stoker "pay for itself—then pay dividends," are covered by the new catalog.

Have you your copy?

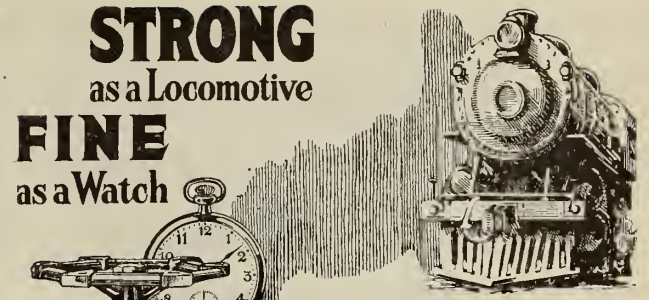
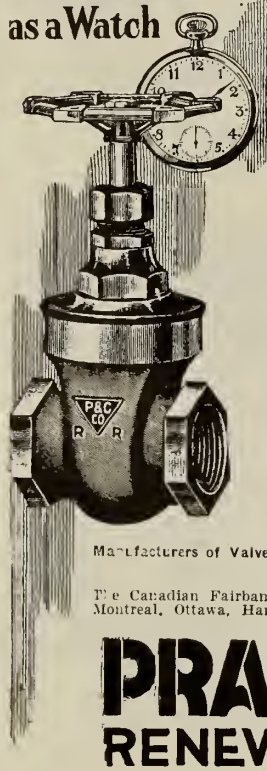
STRONG as a Locomotive FINE as a Watch





For sheer physical strength, plus delicate adjustment, no valve can compare with a Pratt & Cady.
Old-time users of Pratt & Cady Valves who have found valves in their plants as good as the day they were installed, thirty or forty years before, marvel at their durability.
But when you consider their massive construction, the superior grades of metal used, the painstaking labor expended on their construction, and the renewable disc (or renewable seat) feature which practically makes a new valve out of a Pratt & Cady Valve that has seen long service, there is every reason why they should last indefinitely.
Write for our Valve Catalog showing Globe and Gate Valves for every type of service.

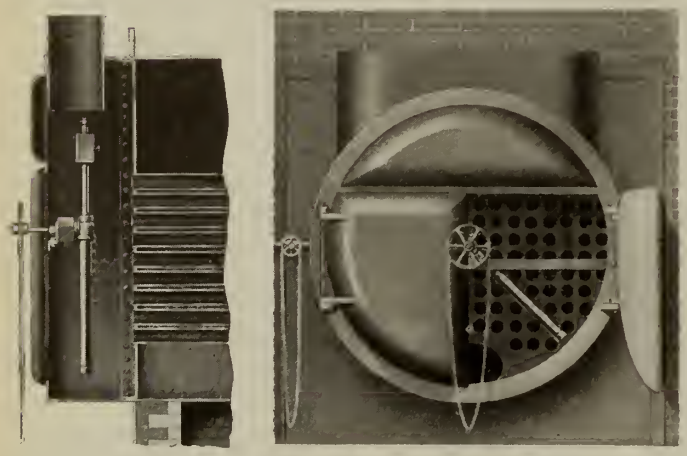
The appalling waste of coal in the operation of Return Tubular Boilers



Some years ago the Engineering Department of the University of Illinois conducted a test of Vulcan Soot Cleaners in Return Tubular Boilers.

For 5 days they allowed soot to accumulate; then 5 when tubes were cleaned daily; then 5 more of no cleaning. The result of that test was conclusive evidence that most Return Tubular boilers, not equipped with soot cleaners, waste an appalling quantity of coal.

The test showed an increase in evaporation due to clean surfaces of 13%. It indicated a DECREASE in coal burned per square foot of grate per hour, due to clean surfaces, of 32.16%. It showed a lowering of stack temperature, due to clean surfaces, of 17.59%.

It is plain that maximum evaporation and minimum coal consumption don't go together when the tube surfaces are heavily coated with soot—a perfect insulator, the most efficient dissipator of heat known! It is obvious that the soot must not merely be removed OCCASIONALLY, as is done with the hand lance, but REGULARLY, at stated intervals, as is done by the Vulcan Cleaner. Without this regular cleaning, soot has time to build up, retard evaporation and increase coal bills.

The owner of Return Tubular boilers that are not equipped with Vulcan Soot Cleaners may take it for granted, therefore, that he is paying for this equipment many times over yearly in lowered efficiency and unnecessary coal wastage.

Ask for a copy of our folder "SPENDING $796 TO SAVE $1,017.40." It is a revelation to the plant owner and engineer of the tremendous possibilities of Vulcan Soot Cleaners as dividend-paying producers.

HOMESTEAD Quarter-Turn Valves

Stay Tight!

Because the seating surfaces are always exposed and subject to cutting and scoring, it is practically impossible to keep globe or gate valves tight for any length of time when the service is severe.

Homestead Quarter-Turn Valves are **seatless.** They stay tight!

Only one-quarter turn of a convenient handle is required to open or close Homestead Valves. Adopt them and you'll save time, trouble and expense.

Homestead Valve Mfg. Company
Homestead, Pa.

Notice how the mechanic handles a Williams' Drop-Forged Wrench. There is confidence in his very grip—he knows the trade mark, W has stood for superior quality for nearly half a century.

Forty different patterns in 1,000 sizes with openings from 3/16 to 7 5/8 inches; a *standard* wrench for all power house service.

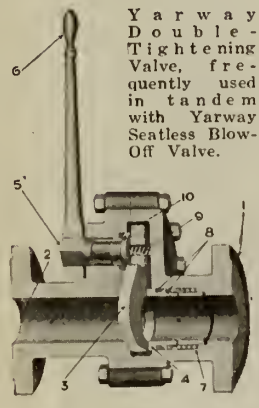
You couldn't do it then but now's your chance



Yarway Double-Tightening Valve, frequently used in tandem with Yarway Seatless Blow-Off Valve.

When the cry was for more production and still more production, 24 hours a day, day in and day out, you only had time for temporary repairs — and not even those could be made like you wanted to make them.

But now's your chance. During the lull after the rush is the time to make these changes and improvements that you have wanted to make and that will prepare you for the next rush period.

Now is the time to replace the old style seat and disc valves with a new YARWAY SEATLESS BLOW-OFF VALVE. With such a valve, the delays caused by reversing, renewing or regrinding seat and disc valves are eliminated altogether, which are a nuisance and a waste even when production is not forced.

Not only are the seat scoring and cutting difficulties of seat and disc valves done away with, but there are other features which make the YARWAY SEATLESS BLOW-OFF VALVES more serviceable. Now is the time to investigate them.

YARNALL-WARING CO.

LEONARD

Can a Barrel be Emptied through the *Bunghole* as *Quickly* as it can be Filled through the Open *Head?*

Seems like a foolish question. Yet this is the principle on which most steam traps are designed—with an opening of only ¼" in the discharge valve while the pipe connection has a 1½" hole. And then you wonder why you require such a large, expensive trap to handle your condensation.

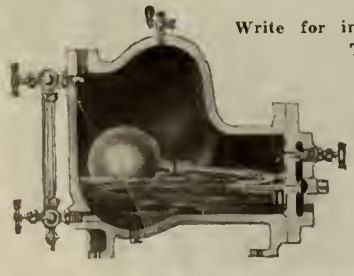
It's different with the American Ideal. Here the valve discharge orifice is much larger than in ordinary traps.

AMERICAN IDEAL STEAM TRAP

has a larger discharge capacity at the different pressures than any other trap having the same size inlet. Consequently you can use a smaller trap of the American Ideal **continuous flow** type than of other makes.

It is the only trap with a powerful enough leverage to operate a valve with such a large orifice.

Because of this powerful leverage, we can use a heavy float, of **thicker, stronger** seamless copper which will withstand a pressure of 600 lbs. to the square inch. This heavier float eliminates the danger of the float collapsing and enables us to guarantee it for the life of the trap.



Write for interesting booklet "A Steam Trap Catechism."

BOWSER
ESTABLISHED 1885

Gives Long Life to Machinery

Good Lubricating Oil, carelessly stored and inefficiently handled, causes more expensive and less efficient lubrication than does ordinary oil, properly stored, and handled according to modern systems of economy.

A Bowser Stream Feed Circulating and Filtration System will solve your problem and give long life to your machinery. Bowser will also cut your fuel costs. Extensive surveys show average savings in fuel costs of five per cent. where stream feed lubrication is in use as compared with hand lubrication methods.

There is a Bowser Circulating and Filtration System for *your* purpose.

Don't Scrap Your Plant Equipment—

Modernize It!

Two courses, in general, are open to effect higher economy and greater capacity in power plant operation. The first method—the scrapping of equipment considered uneconomical or inadequate and replacing it with new, economical apparatus—is seldom justifiable to-day, not only because of high labor and material costs but because recent development of modernizing methods makes available methods whereby improved operation may be obtained at a moderate cost.

The second course—the programme of modernization involves making the best possible use of equipment now in operation by simple and inexpensive conversion—conversion whereby economies and capacities closely approximating those of the most modern plants may be realized at a fraction of the cost involved by a scrapping and rebuilding programme.

Because for their first cost, ELESCO Superheaters render higher net returns than any method known or practiced to obtain economy, ELESCO Superheaters should have first consideration in your modernization programme.

The advantages of superheating are disclosed in Bulletin NT-5, sent at your request.

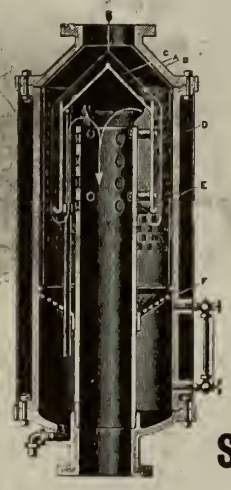
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

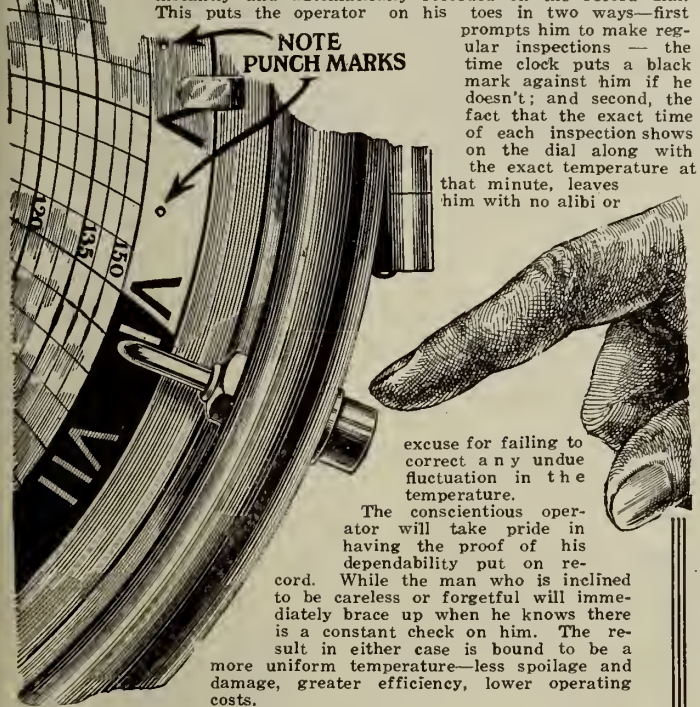
New Time Punch Revolutionizes Recording Thermometers

NOW you can keep a day and night tab on the man responsible for maintaining the correct temperature in your heat-treat process or elsewhere, as well as on the hour to hour and minute to minute variations in the temperature.

The Columbia Recording Thermometer is now equipped with a brand new feature—a TIME PUNCH attachment which makes it a two-in-one instrument that does double duty. It not only records every fluctuation in the temperature, but also shows whether the man in charge has been watching these fluctuations as he should.

Every time the operator inspects the temperature record, he also presses the Time Punch—and the hour and minute is instantly and automatically recorded on the record dial. This puts the operator on his toes in two ways—first prompts him to make regular inspections — the time clock puts a black mark against him if he doesn't; and second, the fact that the exact time of each inspection shows on the dial along with the exact temperature at that minute, leaves him with no alibi or excuse for failing to correct any undue fluctuation in the temperature.



The conscientious operator will take pride in having the proof of his dependability put on record. While the man who is inclined to be careless or forgetful will immediately brace up when he knows there is a constant check on him. The result in either case is bound to be a more uniform temperature—less spoilage and damage, greater efficiency, lower operating costs.

Columbia Recording Thermometers with the new Time Punch cost no more than for an ordinary recorder alone.

Simple, direct and positive in their action.

Every instrument rigidly inspected. Any temperature up to 1000°F. can be recorded accurately.

Columbia Recording Gauges and Tachometers are also equipped with this new Time Punch without extra charge.

Send for Columbia Recording Thermometer Catalog H-33.

WEST VIRGINIA PULP & PAPER CO.

Diamond Soot Blowers Mean Greater Profits

THE big paper mills of the country offer what is probably the surest and most accurate test of the value of any equipment the function of which is to save fuel.

The product of the paper mills is measured in tons, and exact records are kept of the tonnage produced daily, weekly, monthly, and yearly. As the amount of coal delivered to the mill for the production of steam is always known to the ton, it is an extremely easy matter to work out the consumption of coal per ton of paper produced.

To this very fact the remarkable popularity of Diamond Soot Blowers in the paper industry may be traced. The records show that in no other industry is the percentage of Diamond equipped boilers to the total number of boilers in the industry so great. The number of paper mills, the boilers of which are equipped with Diamond Soot Blowers, literally runs into the hundreds. Among the prominent mills equipped with Diamonds are:

St. Regis Paper Company
Detroit Sulphite Company
Hammermill Paper Company
Degrasse Paper Company
Howard Smith Paper Company
American Writing Paper Co.
Rockford Box Board Company
Fitchburg Paper Company
Malone Paper Company
Champion Fibre Company
Riordon Pulp & Paper Company
Schmidt & Ault Paper Company
Kimberly-Clark Company
Filer Fibre Company
Nekoosa-Edwards Paper Co.
West Virginia Pulp & Paper Company

With the paper mills it is a matter of simple arithmetic to determine the saving in fuel per ton of paper effected by the use of Diamond Soot Blowers.

The savings in your own case may possibly be arrived at with equal simplicity. You will find that Diamond Soot Blowers effect the following economies—a saving of 4 to 8 per cent. of fuel—an increase in overall boiler efficiency of 3 to 4 per cent.—a reduction in labor and labor turnover—and a saving in steam required to clean the boiler. Your first step in the reduction of power costs is a general move in the direction of a telephone or a stenographer.

Our branch offices are listed in the telephone books of principal cities. If you write us direct ask for Bulletin No. 280.

Are You Getting DRY Steam?

You know the detrimental effects resulting from accumulated moisture in engine cylinders and turbine casings. If these are your troubles

The **ANDERSON STEAM SEPARATOR**

will quickly banish them.

In the Anderson the moisture is completely separated by the combined action of centrifugal force and the sudden reversal of high velocity steam current—and the moisture cannot be picked up again, when once separated.

Built of thoroughly tested materials the **Anderson** is daily demonstrating its ability to deliver **Dry Steam** under every operating condition. Write for full information.

The V. D. Anderson Co.
1935 West 96th St., Cleveland, Ohio

A Marvel of Simplicity

No Tappets—No Levers

HEPBURN

Patent
VERTICAL RAM FEED PUMPS

have distinguishing features suggested by many years of practical experience. They provide steam users with an outside packed Ram Pump suitably designed for high steam pressures and water of high temperature. Let us tell you all about them and also our Vertical Engines, Compressors, Cranes, etc.

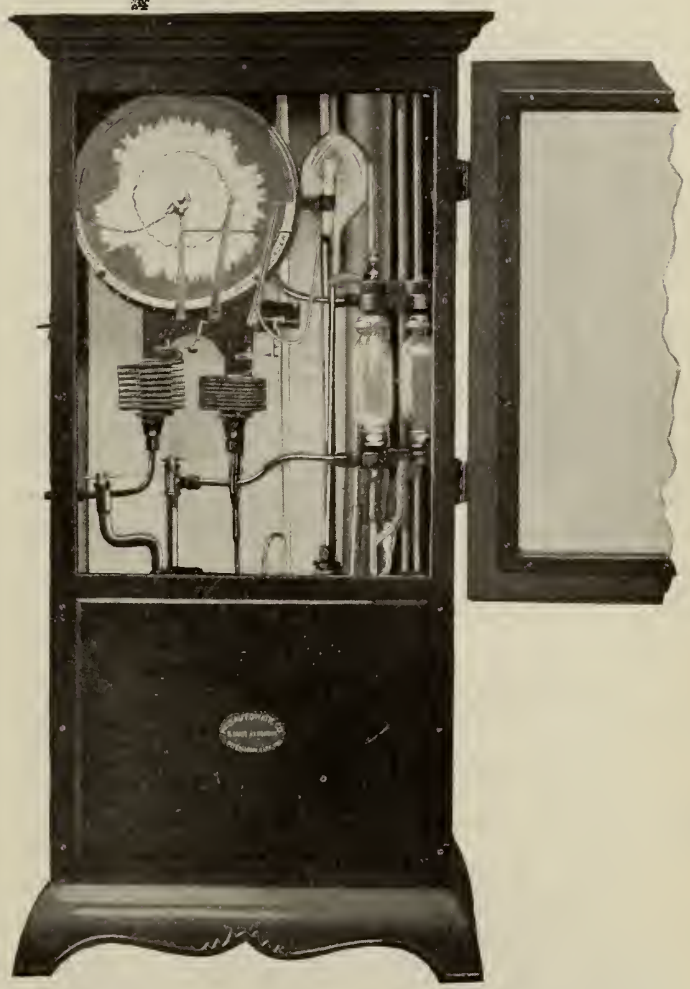
Constant Watchfulness

The Hays Automatic CO_2 and Draft Recorder maintains a constant watch over all the conditions which effect furnace efficiency, keeping a positive record of performance upon which improvements in practice may be based.

This automatic record helps the fire room force to attain the highest efficiency and hold it. It makes good results a continuous matter, which is more important than spasmodic changes. Firemen like it, for improved methods mean better results with less work.



Complete description of the advantages to be gained in your plant will be sent upon request.

2 things to find out about your Steam Traps

1. Do they discharge air and water?

WAIT, now, before you say "yes" to this question. Are you certain that, to prevent air binding, your men aren't letting a little live steam blow through the traps each time they discharge so the air will be carried out with it—or the pet cocks may be left partially open to prevent air binding.

Wasting steam this way may be better than having air-bound traps, but it is expensive.

The simplest, most reliable and cheapest way of keeping steam lines free of air and water is by the use of the Johns-Manville Steam Trap. It discharges the air *with the water*, continuously, and without the familiar but expensive last puff of live steam of ordinary traps.

2. Do they retain steam?

Maybe you say "Yes, if the packing is O. K.," or "If it doesn't stick," or "When the thermostatic member is adjusted properly."

But why even think about packing or mechanisms or adjustments? An efficient trap can be so simple that these considerations are needless.

The Johns-Manville Steam Trap, with no valves, levers or thermostats, just a hollow, floating copper ball, prevents loss of steam. It discharges air and water *as they are received*, without regard to temperature or any other condition except the mere fact that the air and water are in the trap and should be got rid of without losing any steam.

An unattached floating ball is the only moving part of the trap. Part of its surface acts as the valve, its radius as the lever arm and its weight as the counterweight. The forces that control its movement are the buoyant force of the liquid and the unbalanced pressure on the area of the discharge orifice.

When the entering water raises the ball, the discharge orifice is exposed and the water and air are free to flow out of the trap.

When the water level drops, the ball drops, gradually rolling over the discharge orifice, thus throttling down the outflow and maintaining sufficient water in the trap to provide a water seal and prevent the leakage of steam.

Why not have a Johns-Manville engineer consult with you regarding Steam Traps, and tell you about the Johns-Manville Steam Trap and how it will benefit you?

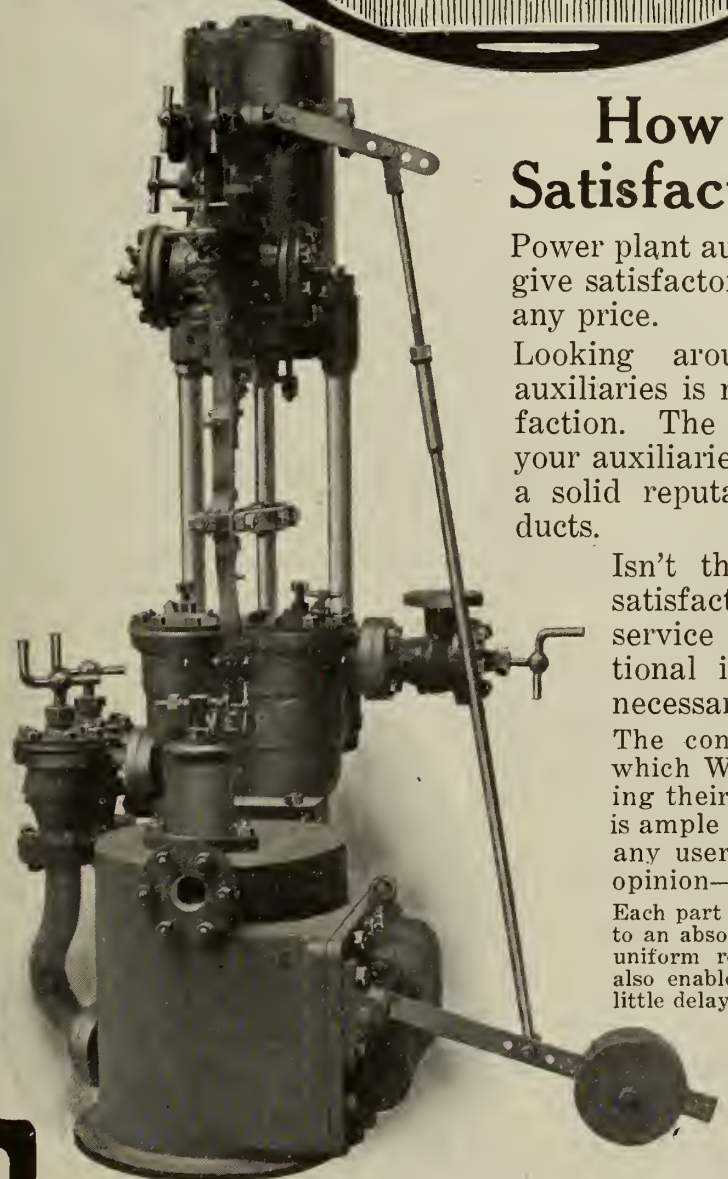
WEIR AUXILIARIES



How Much Is Satisfaction Worth?

Power plant auxiliaries which do not give satisfactory services are dear at any price.

Looking around for "bargain" auxiliaries is not conducive of satisfaction. The sure way is to buy all your auxiliaries from a concern with a solid reputation for quality products.

Isn't the difference between satisfactory and unsatisfactory service worth a slight additional initial expenditure if necessary?

The confidence-inspiring service which Weir products are rendering their users all over the world is ample proof of their merit. Ask any user of Weir products his opinion—

Each part of every Weir product is built to an absolute standard. This guarantees uniform results from all products and also enables repairs to be made with as little delay as possible.

Full particulars of those Weir auxiliaries in which you are interested will gladly be sent.

Power Without Fuel Cost

IF you use live steam for drying, heating water, etc., you are missing a great opportunity to obtain cheap power.

Nearly as many heat units are required to produce a pound of steam at low pressure, as at high pressure. By using high pressure steam and then expanding down through a De Laval Turbine, you can produce power at practically no cost for fuel. The exhaust steam contains no oil and can be used for any purpose where live steam at the same pressure would be used.

De Laval Steam Turbines are used for driving all types of machinery, high and low speed. Large D.C. Generators and Centrifugal Pumps are driven through the De Laval Double-helical Speed-reducing Gears, permitting each part of the apparatus to operate at the best speed for efficiency. Geared turbines are also supplied for rope and belt drives, giving maximum efficiency between steam and shafting.

The steam turbine plant, because of its high economy, efficiency and comparatively low cost, is the best type for auxiliary power. A high degree of skill is not required for its operation, as there are few adjustments, practically no valves or packings, no unbalanced moving parts and a simple and automatic lubricating system. A steam turbine can be started up on short notice without damage.

Our Engineers would be glad to advise you regarding any steam power or pumping problem.

REGRINDING BRASS VALVES

"With Outside Bonnet Construction"
"With the Metal Disc"

Registered and Approved for 200 lbs. Steam Pressure in Ontario and Western Provinces.

THE PENBERTHY REGRINDING LINE is designed to meet the demand among power plant operators for a valve that HOLDS UP under high steam pressure and severe conditions. They are made from the best quality of steam metal, which is generously distributed so that parts subjected to the greatest strain and wear have proportionately heavier walls. The union bonnet ring which secures bonnet to body is of heavy design and this outside bonnet construction (found in all Penberthy Valves) is acknowledged by leading engineers to be the safest, and most practical improvement made in brass valves in generations past.

We Were the First

To manufacture in Canada this high grade line of brass valves and the demand is ever increasing, owing to the reliable and dependable service they give under high pressures and severe conditions.

BE SURE THIS NAME IS ON THE VALVE YOU BUY

Multiflow Heaters
Evaporators and Distillers

Insure Satisfaction

Every Weir Marine Auxiliary you use is as good as an insurance policy. It benefits both owner and engineer by giving added service—and the only premium you pay is its first cost.

Take Weir Pumps for instance. The service which they are rendering their 65,000 users all over the world proves their efficiency. Watch them at work: don't their slow, steady, powerful strokes convince you that their every installation will assure you of satisfactory pumping?

Each part of every Weir auxiliary is built to an absolute standard. This guarantees uniform results and also enables repairs to be made with as little delay as possible.

Full particulars of those Weir Products in which you are interested will gladly be sent upon request.

Full Time and Overtime

HEAVY service imposes a tremendous strain on your plant machinery. Every individual part of every unit must be properly lubricated to carry the load.

Scientific selection of your lubricating oils is every bit as important as the careful choice of mechanical units themselves.

Imperial Lubricants, backed up by Imperial Service, will solve your lubricating problems. Increased production, minimum depreciation and lowered lubricating costs surely follow.

There's a right grade of oil for every service condition; the quality is always uniform, with ample supplies conveniently available. Imperial Lubrication Engineers will gladly advise you on all lubricating problems.

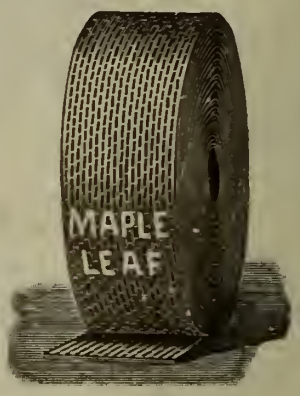
Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO., Ltd., Hamilton, Canada - Quebec Branch: 51 Duluth Bldg., Montreal

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel

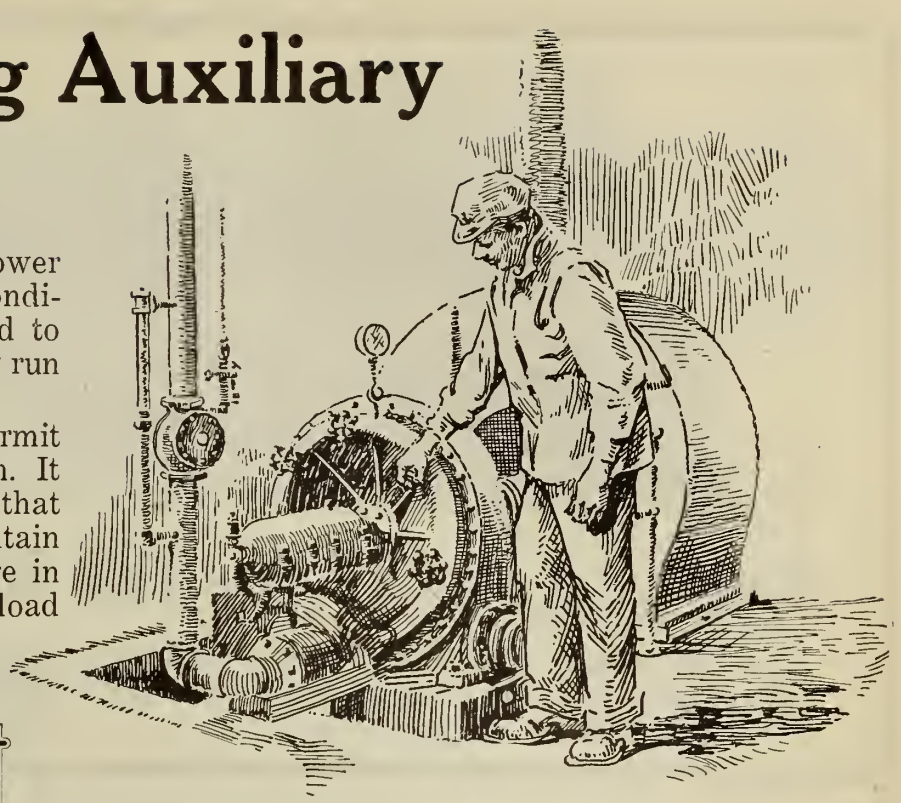
Steam Saving Auxiliary Drives

The auxiliaries in the modern power plant seldom operate under ideal conditions. Most of them are subjected to severe load fluctuations and usually run underloaded.

The high price of coal does not permit extravagance in steam consumption. It is therefore extremely important that the drives selected are able to maintain a good economy over a wide range in load. Operate at nearly full load economy at one-quarter and one-half load.



Sturtevant
(TRADE MARK)

Steam Turbines

They are not controlled by throttling down the steam, but by shutting off one or more of the several steam nozzles by the hand wheels on the turbine casing. The nozzles remaining in service undergo no change in efficiency.

The turbines are scientifically designed and all parts are constructed accurately to gauge of the best obtainable materials.

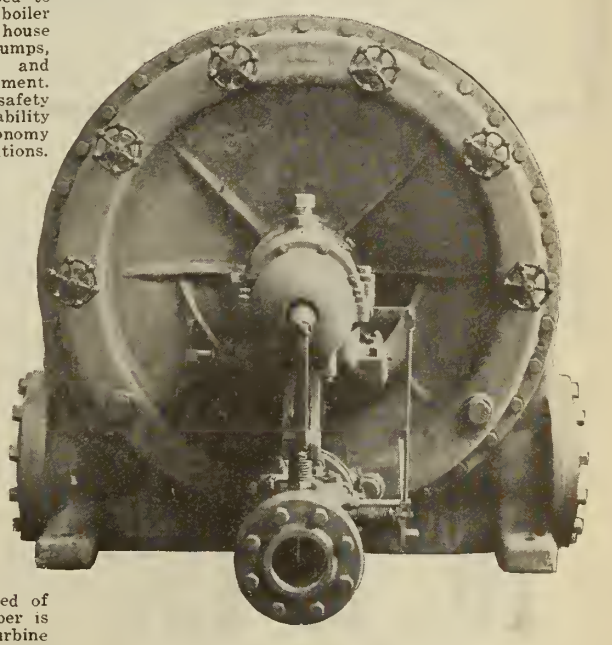
The assembly is made under expert supervision and a true running balance is established.

A positively dependable shaft governor holds the speed regulation within close limits and entirely adapts these turbines to drive electric generators.

Consultation with our engineers is recommended before selecting any turbine drive.

Write for Bulletin.

Sturtevant Steam Turbines are used to drive exciters, boiler feed pumps, house pumps, fire pumps, fans, blowers and special equipment. They combine safety and dependability with high economy under all conditions.



When the speed of the driven member is below the turbine speed Sturtevant Transmission Gears are used to obtain maximum efficiency.

P&H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

P&H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

Quarter-Turn Valves

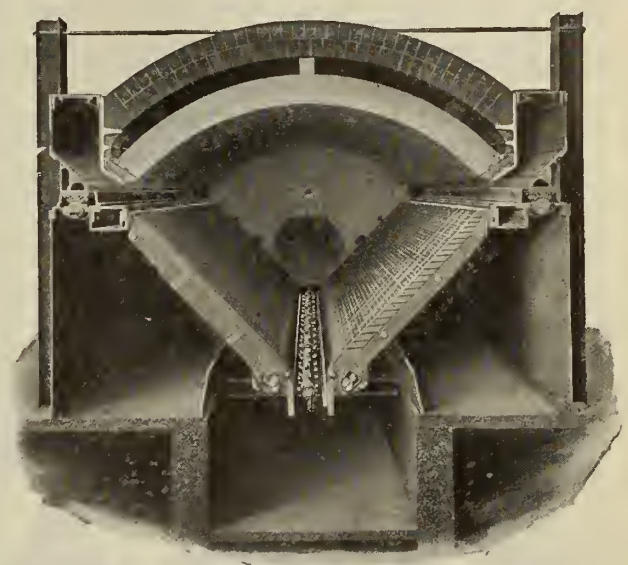
Eliminate Waste Time and Leakage

HOMESTEAD Valves close with a quarter-turn and remain tight without dripping or leaking. A single quarter-turn of the lever opens them to a straight, unobstructed flow.

Made in straightway, threeway and fourway patterns for air, steam, water, oil, gas or acids. Catalog upon request.

Homestead Valve Mfg. Company
Homestead, Pa.

Reducing the Cost of Steam Making



Back in 1907 the New York Air Brake Co. became interested in the possibilities of savings to be made by using

MURPHY AUTOMATIC FURNACES

in place of hand-firing methods. A test made on a 150 h.p. boiler, hand-fired, showed a cost of 20.39 cents per 100 lbs. water evaporated. A Murphy was then put in under this same boiler, reducing the cost to 14.49 cents per 100 lbs. of water evaporated.

This **demonstrated saving,** together with smokeless operation and low maintenance, has led to **three repeat orders** received from this company.

At that time coal cost $2.95 a ton at their plant—to-day that won't cover the freight per ton to most plants.

Think how much more the Murphy can save at to-day's coal prices!

Find out what a Murphy can do for you in your plant. Send for Catalog HM-5.

For information on RILEY UNDERFEED STOKERS for large boilers, see advertisement in last issue or send for RILEY STOKER Catalogue HR-5.

It's Your Money --- Take Your Choice

This is the story of Vulcan Soot Cleaners—in a nutshell.

If your plant isn't Vulcan-equipped, you're up against the drawbacks listed at the left.

When your boilers are Vulcan-equipped, you're assured of the advantages listed at the right.

Whatever may be the generally good operating conditions of your boilers, it is impossible to maintain maximum results by hand blowing.

It is only through the installation of mechanical soot cleaners—Vulcans—that steam production can be maintained and fuel saved at the same time.

The lack of Vulcan Soot Cleaners in your boilers spells W-A-S-T-E!

Can you afford it?

Let us tell you all about Vulcans and what they can accomplish for you.

Please mention type of boiler, steam pressure, and number of tubes high and wide.

DURABLA

Have You a Feed Water Problem?

If it concerns a pump, here is the answer.

The COPPUS Centrifugal Turbo Boiler Feed Pump specially constructed for boiler feed work, simple, compact and with a single rotating element.

It occupies a fraction of the floor space of other pumps, reciprocating, turbine, or motor driven, and runs continuously without vibration or pulsation in the feed line, which in itself is a decided advantage.

A keen judge of pumps will recognize its superiority for boiler feed work. It is built as a single unit with the turbine wheel and pump impeller on the same shaft—with only one stuffing box that does not require repacking.

Every COPPUS Pump is equipped with an excess pressure governor and an automatic safety stop valve, insuring efficient operation, automatic control and positive safety.

Results prove that we have developed a simple pump of high efficiency—just the pump that power plant engineers need for their feed water supply.

Further detailed information will be gladly given on request.

Extravagance Must Stop!

THE COPES Boiler Feed REGULATOR

is a vital organ in the system which draws the latent energy out of the coal pile and delivers it at the bus bar or the main drive shaft.

Without the Copes Boiler Feed Regulator none of the other organs can perform its function properly. Stokers, feed water heaters, water softeners, and the boilers themselves cannot do their best without proper feed water regulation. The legibility of steam and water flow records, pressure and temperature charts, all depend more or less on scientific feed water regulation.

For complete information about COPES BOILER FEED REGULATORS, ask for Bulletin D.

"Canada Holds the Key"

Agnes C. Laut, in the May 15th issue of MACLEAN'S MAGAZINE, uses figures and facts that prove the future heart-beats of the great oil-burning leviathans of the ocean lanes will depend on the lakes of fuel that will be sucked up from the "basement" of Northwestern Canada. In an article, "Strangling Our Oil Goose," Miss Laut emphasizes:

"Canada has the oil. Canada holds the naval and merchant marine key of America. Edmonton in your generation and in mine will be a second Pittsburg. Great tankers will float out from Prince Rupert to supply the Orient. Tank cars will become as common across our prairies as grain cars. Our National Railways will—"

But you will have to read this talented author's article to get the picture she visualizes of the future of Western Canada when the development of oil resources of the North is at its zenith.

There is a strong hint in this article of Miss Laut's that Canada may "strangle her oil goose" by too much so-called caution. Read MACLEAN'S MAGAZINE, May 15th, and discover how Miss Laut argues that Canada will spoil her chances for control of the oil situation in North America and great wealth—if she *is not careful.*

A Tempting Array of Fact and Fiction

Take a peep into the May 15th issue of MACLEAN'S! Besides Miss Laut's article:

"He Who Laughs Last-----!"
By Frederick William Wallace

A thrilling short story of action. Setting, the Atlantic coast; characters, deep-sea fishermen. Written by the dean of deep-sea short fiction writers.

"Canada Counts Noses"
By Nicholas North

Did you know that the first systematic census of people and their wealth was taken in what is now the Dominion of Canada in 1666, and that system was later copied by all the greater world nations? Read this article on census-taking in Canada and learn all about it.

"Neighbor's Wooing"
By Francis Dickie

A race-track story in which you can fairly hear the rhythmical hoof-beats of the contending horses as they pound around the course. There's a beautiful, scheming young woman in this story and some plot!

"The Slant-Eyed Man"
By Leslie Howard Gordon

This is the second in the series of "The Gates of Tien T'ze" stories. There's mystery here that keeps you guessing right up to the climax.

"Pawned"

Another generous instalment of Frank L. Packard's mystery-romance.

"Peacock's Pinnacle"
By M. O. Hammond

Here's the absorbing story of a director of the Bank of England who "was once a barefoot boy" in the hills of Glengarry. Read how this barefoot lad, who built castles in the air, and by dint of his own efforts, made every dream come true.

"The Legion of the Lost"
By J. L. Rutledge

Why do men disappear? Sometimes it's premeditated action on the part of the individual, committed for the same reason as suicide. At other times it's accident—and then again, there are grim disappearances that are never solved. In real life the long arm of coincidence often plays a role that baffles the detectives.

"Our Lower Prices Bogey"
By Charles Christopher Jenkins

Who's to be blamed for the falling off in demand for certain necessities? What caused the slump in wages in many lines of industry? Read this article in which is described the "Deadly Circle" to blame for the passing depression. The article includes a resumé of the situation from leading employers and labor leaders.

"Son of the Clackmannan Giant"
By Stanley R. Hofflund

Do you like prize-fight stories? Maybe you don't care for the brutal sort, but here's one that is different of a prize-fighter with a soul and a woman at stake.

Review of Reviews

Included with this exceptional line-up of intellectual information and entertainment are the regular features of MACLEAN'S—the "Review of Reviews"—a comprehensive summary of the world's best contemporary short articles:

GOOD PRACTICE

It is good practice and practical economy to use only **the best** in construction.

For seventy years "REED'S" has been THE STANDARD of Canadian Engineers and Architects.

ROOFS, VENTILATORS, SKYLIGHTS AND EXHAUST SYSTEM BY GEO. W. REED & CO., LIMITED.

"REED" Roofs, Exhaust Systems, Mill Floors, Skylights, Ventilators, Fire Doors, etc., have stood the most severe and exacting tests, and have proven themselves the most economical in the long run. The recollection of quality and service remains long after the cost is forgotten.

Engineers, Architects, and Power Plant Superintendents will do well to consult us before completing plans for new buildlings, alterations or repairs.

Our Engineering Staff is at your service—gratis.

GEO. W. REED & CO., Limited, Montreal

Keep Your Boilers Clean

What the Sherwin-Williams Co., Ltd., largest manufacturers of paint in America, say about

MILLER'S BOILER CLEANING EXTRACT

R. C. Miller Oil & Supply Co.
Montreal.

May 5th.

Gentlemen:

Replying to your inquiry regarding results obtained from the use of your "Boiler Cleaning Extract" in our steam boilers.

We are pleased to be able to state that we have had entire satisfaction, and that this "Extract" has removed all of the scale from our boilers, and prevented any from again forming, and also that there has been no damage whatever caused to any part of the boilers, including the Tubes, Plates, Joints, Valves, Packings, or Brasses.

We find that it was a good investment as it reduced the consumption of coal, lengthened the life of the boilers and saved costly repairs.

Yours respectfully,
(Signed) Sherwin-Williams Co. of Canada, Ltd.

R. C. Miller Oil & Supply Co.
MONTREAL

Who was the Third Man?

WHEN the retirement of Sir Robert Borden as Premier of Canada was first announced, three outstanding men were considered as his possible successors. Their names were displayed prominently in every Canadian newspaper. The present Premier was of course one of the men mentioned. Sir Geo. Foster another. Who was the third man? You would remember him no doubt if his name were displayed prominently in the daily press to-day—but he has retired from the political arena, and his name is seldom mentioned.

How easily names slip from the memory when they cease to be given publicity.

There is a lesson here. If you wish your name and the name of your products to be remembered, you must give them constant publicity.

The prudent manufacturer of machine tools, power plant equipment, or industrial supplies of any kind places his name and the name of his products where they will be seen and remembered to best advantage: **in reliable technical newspapers.**

Reliable technical newspapers in Canada are those included as members of Canadian National Newspapers and Periodicals Association. Their circulation is bona-fide and their editorial practice is carefully guarded, in fact their whole policy must conform to the highest standards else they would not be eligible to membership in the association.

Canadian Machinery

Power House

Canadian Foundryman

Marine Engineering

Each of these technical newspapers is a member of the Canadian National Newspapers and Periodicals Association.

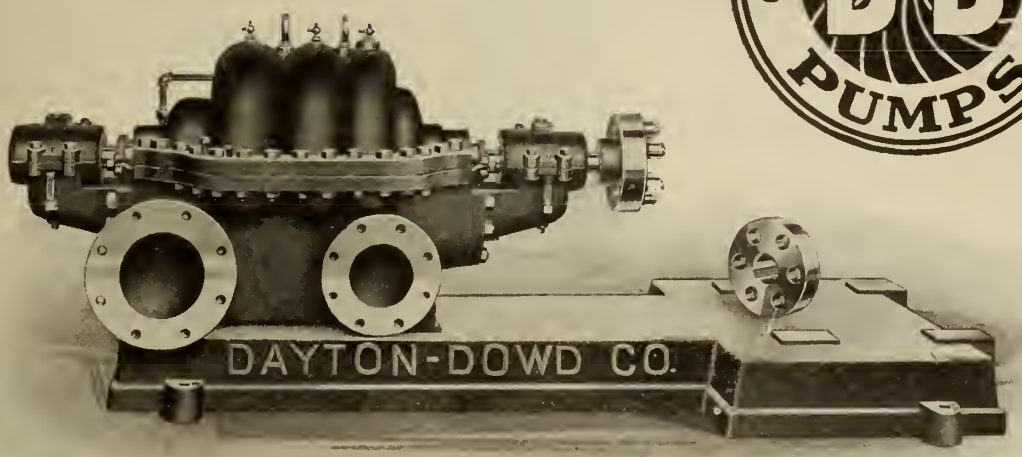
DAYTON-DOWD

CENTRIFUGAL DD PUMPS



Type C.S.U. Automatically Balanced Three-Stage Centrifugal Pump

With Extended Bed Plate for Direct Connection to Motive Power

FOR service where the total head is beyond the range of efficient application of the Dayton-Dowd C. S. Single-Stage Pumps, the number of stages being dependent on the head and speed available to drive the pump.

The compact design of C. S. U. pumps, discharge and suction openings being on the same side of the case, permit operation in series with the greatest ease—the piping being in a direct line.

The transformation of the kinetic energy of the water (due to its velocity) into pressure, is very efficiently accomplished in type C S U Multi-Stage pumps by taking full advantage of the old turbine principle in a new application, whereby the diffusion vane effect is obtained without intricate and costly construction. The high permanent efficiency of type C S U pumps is due to this original construction; and the absence of diffusion vanes adds greatly to their life and reduces the expense of maintenance to a minimum.

Bulletin 241 gives full information—have us send it to you.

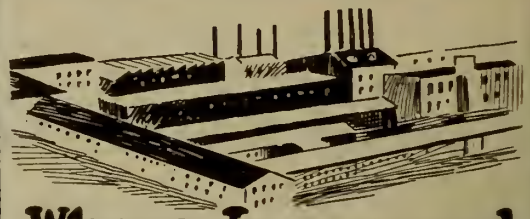
THE ARTHUR S. LEITCH LIMITED

1001-2 Kent Building, TORONTO, ONTARIO

Which Is

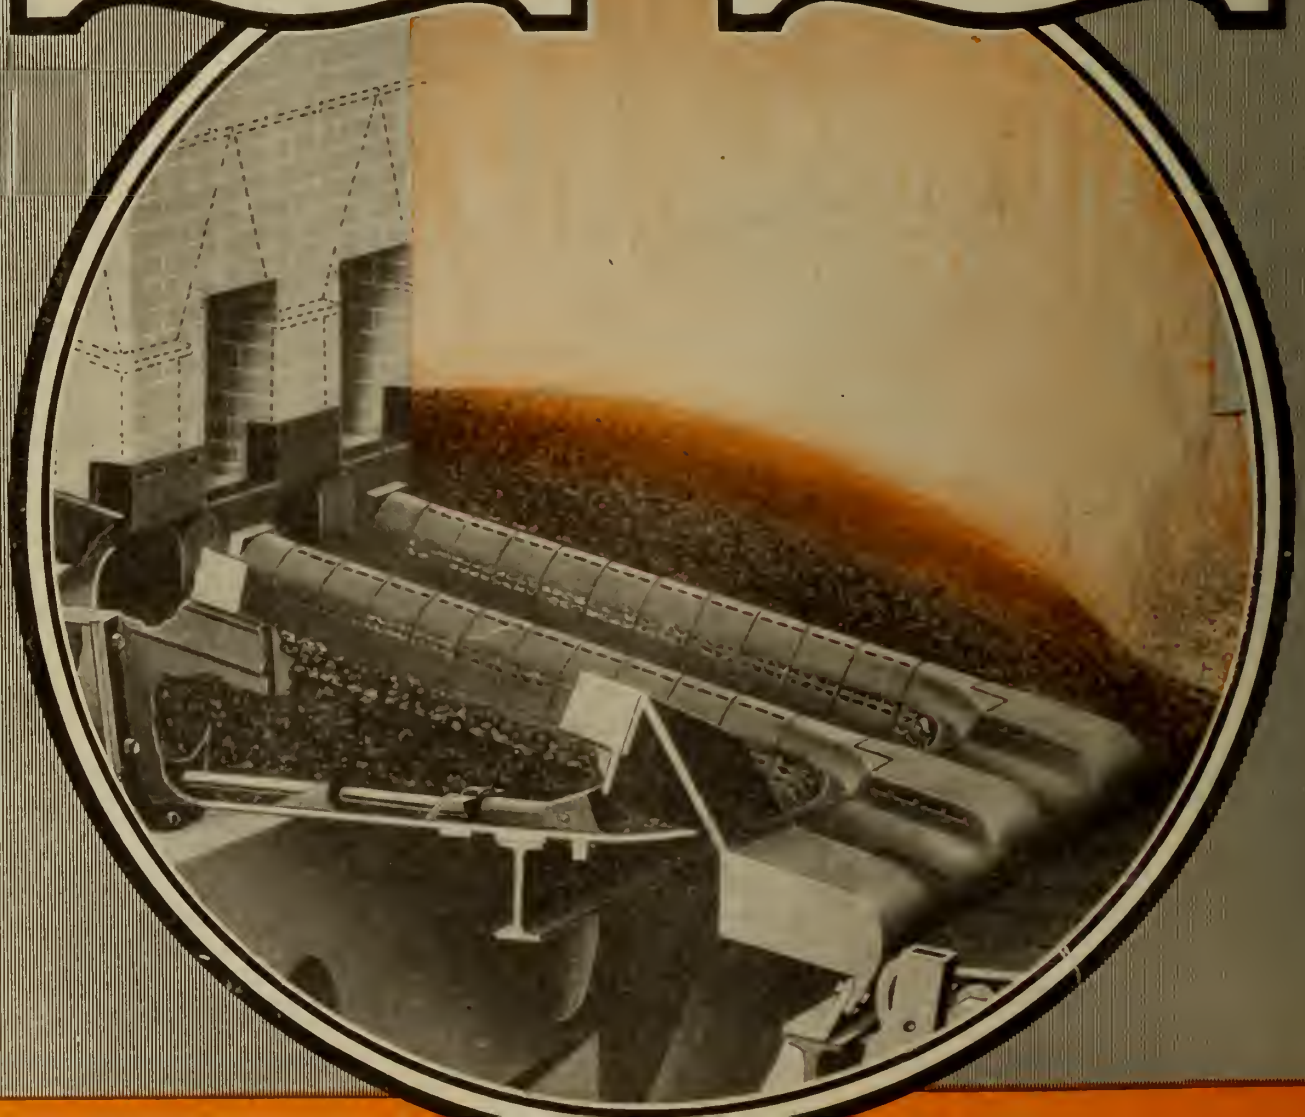
Where the Peak Load is the Rule

Canadian Central Stations and Public Utility Plants in general will find the Jones "A-C" exactly suited to the fluctuating load. The automatic control of fuel and air in the Jones "A-C," and individual control of retorts provide unequalled flexibility. From banked fires to 300 per cent. of boiler rating in a very few minutes is typical Jones performance.



Where Increased Production Calls for Continuous Over Loads

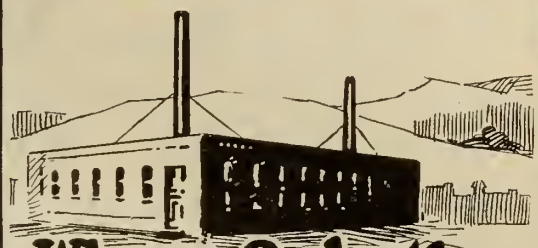
Large Canadian Industrial Plants operated at peak capacity will find the ability to operate continuously a marked advantage. The "automatic-cleaning" feature of the Jones "A-C" and the extreme simplicity eliminating shutdowns, permit continuous operation at high capacity. Two hundred per cent. of rating for 24 hours a day is regular practice in many Jones-equipped plants.



Your Plant?

Where Smokeless Operation Ranks First

The Jones "A-C" is the ideal stoker where rigid smoke ordinances are in force. The under-feed principle of combustion, as originated and perfected in the Jones Stoker, insures smokeless operation. In the words of one Jones user, "We have boosted our load from 150 per cent. of rating to 340 per cent. in eight minutes without visible smoke."



Where Only the Lowest Grades of Fuel are Available

The smaller isolated plants, limited to a single fuel diet, offer a great field for the Jones "A-C." The Jones "A-C" insures complete combustion of the lowest grade fuels, and permits the firing of high-ash coals without clinker trouble. Bone coals containing as high as 41 per cent. ash have been burned efficiently.

Saves Coal for Plants of Every Type and Size

TO-DAY stoker firing is an acknowledged economic necessity—not alone stoker firing, but *high duty stoker firing.*

Hand firing is being discarded in Canadian Plants because with present-day coal and labor costs, plant owners have found they can no longer afford hand firing. If you cannot afford hand firing, you cannot afford to be without the high-duty—

Jones "A-C" Stoker

MADE IN CANADA BY CANADIANS—SOLD FOR CANADIAN MONEY AT PAR

The stoker that combines the fundamental advantages of all types, while sacrificing the incidental advantages of none, is naturally the best for any plant. It is because the Jones "A-C" (Automatic-Cleaning) Stoker has had the advantage of 25 years of development by an organization comprised entirely of engineers—because our experience has covered every conceivable variation of load and fuel condition—because the under-feed principle, originated by this Company, has become universally accepted, that we claim the Jones "A-C" to be exactly such a stoker.

Your stoker firing problem probably falls within one of the four general classes described above. Jones "A-C" Stokers meet the requirements of each class. Write for catalog.

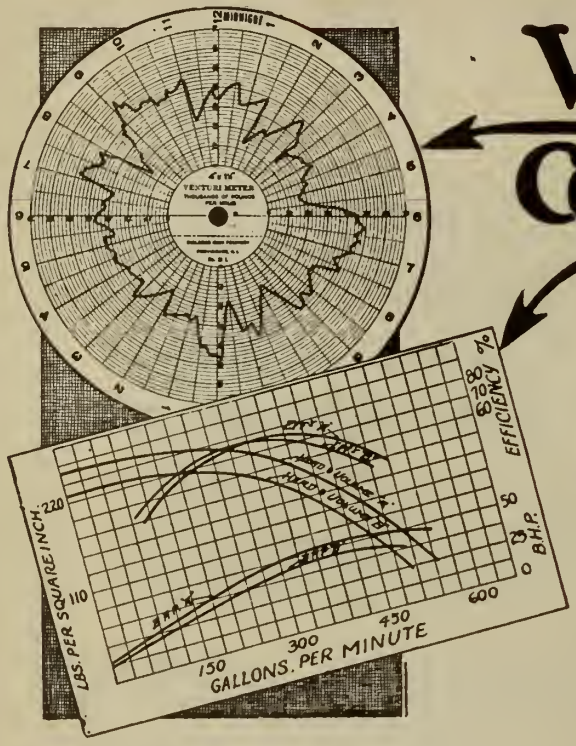
JONES STOKER



Variable Volume Constant Efficiency

THE REES RoTURBo

A Centrifugal Pump for Any Service

IN the "Rees-RoTURBo" we have the very latest development in centrifugal pump design. The disadvantages of the ordinary pump have been entirely overcome and it meets perfectly the conditions of to-day for high efficiency

The fluid velocities are low, reducing friction losses to a minimum, and there is no wear even from gritty water, and high permanent efficiency is maintained. This means that the "Rees-RoTURBo" is ideal for multi-stage operation and may be said to be a pump for any service.

Should there be ony point on which you would like to be enlightened, our engineering deportment is always ot your service and without any obligation on your port we heortily invite enquiries.

Before Going Into the Analysis of Valve Setting by the Indicator Card, a Short Description of the Indicator is Given, With its Accessories

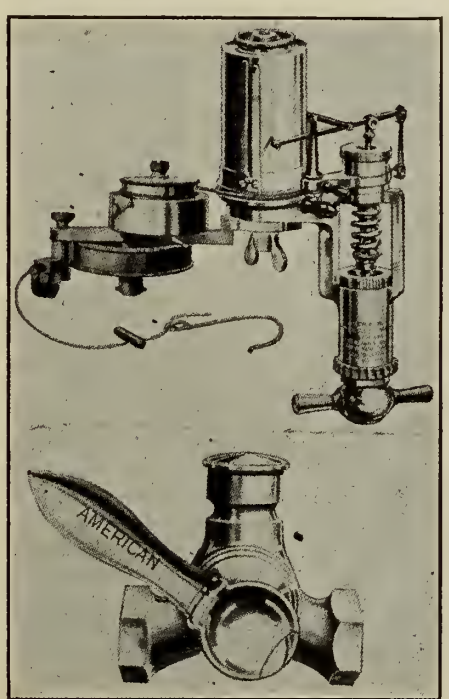
By T. H. FENNER

WE have described the general method of valve setting, preliminary to turning the engine over by steam and getting an indicator card. Before going on with the use of the indicator to determine valve setting, we will give a short description of the instrument itself.

The Steam Indicator

The indicator consists essentially of two distinct parts; the cylinder, which has a piston to transmit the expansive force or pressure of the steam to the recording pencil, and a drum, which is driven from the moving part of the engine. The drum is to receive the paper on which the diagram is traced, and it moves through a certain part of a revolution with every stroke of the engine. The length of the diagram taken depends on the arc turned through by the drum, and the latter is determined by the reducing mechanism of the indicator.

The action of the steam on the piston of the indicator is resisted by a spring, which is placed on the piston rod. These springs are of different degrees of resistance according to the pressure of the steam. Some are made so that a pressure of 100 pounds per square inch on the piston will compress them through one inch, others so that 80 pounds will do the same, and so on down through 60, 40, 20 and 10 pounds per square inch. The springs most frequently used are 80, 40, and 10, for high, intermediate and low pressure cylinders. The size of spring chosen should be such that a diagram about two inches in height is obtained, while at the same time the spring should not be weak enough to give sudden distortions of the pencil, or, to be plainer, violent jumps and drops. If this occurs, a misleading diagram will be obtained. Supposing you are about to indicate an engine carrying an initial pressure of 150 pounds per square inch, and you have springs of 80, 60, 40 and 20 pounds to choose from. An 80-pound spring will give a diagram about 1¾ inches high at its highest point. A 60-pound spring would give a height of 2½ inches, but the spring being light compared to the initial pressure, may give a momentarily



TYPICAL INDICATOR AND THREE-WAY COCK.

higher reading than the actual initial pressure. Then the 80-pound spring would be the one to use. If you want a card two inches in height, and have an initial pressure of 100 pounds, then you would want a spring $100 \div 2 = 50$ pounds. Probably you would not have one this size, the nearest being 40 and 60. It would be better to use the 60-pound spring, for the reason just given. On the other hand, if the spring used is too heavy, giving a low card, the various points of distribution will be more difficult to see.

The outline diagram here shown gives the general particulars of the indicator construction. The bottom of the cylinder is formed with a union connection, to connect to the three-way cock of the cylinder. The piston, which is of bronze, is made a neat working fit in the bore, and steam tightness is obtained by turning a small groove in the circumference. In an indicator with an inside spring, the spring is screwed on the base of the piston rod, and its other end to the cylinder cover. An extension or lug on the cylinder carries the drum for the card. The piston rod is connected outside the cylinder to the parallel motion which carries the pencil. This parallel motion is that invented by Watt for his pumping engines, and it gives the pencil point exactly the same motion as the piston. Sometimes the spring is placed outside the cylinder instead of inside, as in the illustration, and in this case the piston rod is extended to carry the spring, the link motion being just the same. The object of carrying the spring outside the cylinder, is of course, to get away from the action of high temperature steam on the delicate spring.

The drum that carries the paper is mounted on a central spindle, round which it turns. A spring is connected at one end to the spindle, and at the other to the periphery of the drum. When the drum revolves it coils the spring, and the spring brings it back during the return stroke of the engine. The drum is driven by a cord attached to the lower part of the drum, and wound round it a couple of turns, while its free end is attached to some part of the engine which has a reciprocating motion. If not attached direct to the engine, it is attached to some reducing apparatus which is in turn attached to the engine itself. As the drum is usually only about 1½ to 2 inches diameter, and it does not make a complete revolution, it cannot travel the same distance as the crosshead. It usually travels from 4½ to 5½ inches and the stroke of the engine may be from 12

to 48 inches, or even more. Hence the necessity of reducing motions.

Reducing Gears.

The means of reducing the motion of the crosshead to that of the drum are various, but the type where the gear is a part of the indicator itself is coming into general use more and more. This is quite natural, as it is by far the most simple and convenient.

In this arrangement, the indicator cord instead of being attached directly to the paper drum of the indicator, is attached to a pulley which drives the paper drum through a pair of bevel wheels. The pulley attached to the large bevel gear drives the paper drum, and this pulley can be changed to suit any engine from twelve inches to six feet stroke. The bevel gear spindle is attached to a spring which brings it back to starting position in the same way that the drum is brought back.

The crosshead motion may also be reduced by means of a lever attached to the crosshead itself, and if the indicator is not supplied with a geared-reducing motion, this is about as good a way as can be used. The top of the lever is pivoted to a bracket made on the frame of the engine, and the lower end is driven by a pin from the crosshead. The great point about the geared reduction device is that there is no point for any lost motion to take place, and the motion of the drum exactly coincides with the motion of the piston. Whatever method may be used for making the reduction, care must be taken that there is the least possible chance for lost motion.

Taking the Card

One of the points that beginners find awkward is attaching and detaching the cord to the moving part which drives it. This is especially the case in fast-running engines. There is no great difficulty if the cord is properly arranged, and a little practice will soon make the average man proficient. When the motion is driven directly from the crosshead on a high-speed short-stroke engine it is of course more awkward than on a slow speed long stroke engine, where a lever of some kind is perhaps used. However, this is one of the things we believe must be learned on the job, and cannot be taught through the written word. To those who have not yet taken a card, we can only say, "Get the chief to show you how."

Before taking a card the indicator should be warmed up by opening the indicator cock very slightly, and allowing the steam to enter the indicator cylinder. Leave it like this for 15 minutes or longer, till the indicator has got thoroughly heated up all over, and the pipes from each end of the cylinder to the three-way cock are thoroughly clear of moisture. Then shut the cock, and place the card on the drum. Next attach the cord to the driving motion, and without opening the three-way cock, place the pencil on the drum and a line will be drawn. This is the atmospheric line, or the line that represents a pressure of 14.7 pounds absolute. It is the datum line from which can be set off by means of the scale the absolute zero, or vacuum line. This line must never be omitted when anything in the nature of calculations are to be performed on the card. Even if the card is to be used for observing steam distribution only, it is better to have the line on, and as a matter of fact, it becomes a habit to always place it on the card first thing. It is a good guide as to whether the pencil is set right before taking the card, that is, set so as to make a clear definite mark.

When taking the first card, after the atmospheric line has been made, it is a good plan to disconnect the cord again, and examine the position of the atmospheric line with reference to the length of the card.

It sometimes happens if the length of the driving cord is not quite correct, that on the inward stroke of the engine the drum comes to rest against its stop before the crosshead has completed its inward stroke. It may be such a small fraction of time that it is not noticed, but it can be checked up very nicely by the atmospheric line. Pull the drum around by hand, and then allow it to go back slowly, keeping the atmospheric line in view and the pencil point resting lightly on it. If the end of the line reaches the pencil point before the drum has reached its stop, you are all right. If, however, the drum comes up against its stop at the same time that the line end reaches the pencil point, then the cord must be shortened. Sometimes a very straight steam line is due to this cause and this only. The engine stroke must be finished while there is still some movement in the drum, to get a true card.

Having satisfied this condition, the cord can be again connected, and the cock opened to the cylinder. The pencil is pressed lightly against the card, and kept there for a couple or three revolutions. The cock is then opened on the other end, and the same thing takes place. The cock is closed, the cord disconnected, and the card taken off the drum. We can now see how close the valve or valves are to being set correctly, providing we can correctly read the message the card can give us.

TESTING CENTRIFUGAL PUMPS

In the current isssue of Beardmore News there is described the method by which centrifugal pumps are tested in the Coatbridge works of Messrs. William Beardmore & Co. The pump is driven by a variable speed motor, so that any test speed desired may be obtained. By reading the electrical power input and using it in conjunction with the certified efficiency curve for the motor, the actual brake horse-power given off by the motor is ascertained. The volume delivered is measured most accurately by a method introduced and brought to perfection by the late Professor James Thomson, of Glasgow University. In this method the water flows from the tank over a right-angled V notch, the quantity passing depending on the height of the water surface over the apex of the notch. In the Beardmore test plant the water from the delivery pipe flows into the end of the tank remote from the notch, passes through three fine wire screens about one foot apart, and then flows steadily down the tank and over the notch. The screens take all surge and eddy motion out of the water, with the result that the flow over the notch is perfectly steady. The height of the water level over the apex of the notch is accurately measured at a point three feet back from the notch, so that still water conditions are obtained, and the readings are not rendered inaccurate by the fall of water level in the immediate vicinity of the notch. The device for measuring the height is calibrated direct in gallons per minute, in accordance with formulae devised by Professor Thomson.

Very instructive results, it is added, may be obtained from exhaustive tests of pumps on well-arranged and reliable test plants, such as that described, and it is owing to such tests, in conjunction with careful and intelligent design, that the efficiency of the centrifugal pump has been raised from the 40 per cent. which was common a few years ago, and still obtains in some designs, to the much more satisfactory efficiencies of to-day.

THE SILENT EXHAUST

The problem of silencing the exhaust from internal combustion engines has engaged the attention of engineers for many years and countless devices have been invented, with more or less success, for the purpose. Hitherto the appliances required for the marine type of internal combustion engine have occupied a good deal of space and added considerably to the weight of the vessel. In order to overcome these drawbacks a British firm of engineers has devised appliances in which the energy of the exhaust gases are used to put in motion a comparatively large body of cooling water or air. The exhaust gases are forced to come out from below a large spring-loaded valve in a stream between two plates under water, inducing the water to circulate and cooling themselves at the same time. The only resistance offered to the flow of the gases is the light resistance of the spring and of a few inches of water, so that very little back pressure is exercised. Where air cooling is used, a similar principle is adopted. Both types have been successfully at work for some time, the former on engines up to 10,000 brake horse power and the latter on engines of 1,500 brake horse power.

Practical Points on Steam Turbines

Operating Features of Steam Turbines—Warming Up—Function of the Relief Valve—A Turbine Explosion—The Gland Packing —End Play—The Emergency Governor

By J. A. McGILLIVRAY

A FEW remarks on the operation of turbines may interest the engineer who may not just now have turbines in his charge, but may later on. I would advise him to buy a book on steam turbines if there were any that could be recommended for the operator on the job. If there are such books I never saw them. There are a great many books "and excellent ones at that" which tell you all about how they are built and how designed for economy and all about the method by which the steam is expanded through successive stages or in a single nozzle, etc. I am not taking that matter up just now, because the operator when he has the turbine as part of his equipment is most concerned with successful operation and least concerned with the particular features of design.

First let me say that there are no two steam turbines in existence that have the same peculiarities, any more than there are any two people having the same nature, but there are many things that are common to all steam turbines and some of these things we will discuss.

Warming Up

To warm a turbine up before putting in operation, or bringing her up to speed, is an entirely different operation to warming up the engine. The engine must be warmed up before starting, but the turbine should be warmed up running, or turning over. The reason for this is that it is impossible to get equal temperature or nearly equal temperature if the throttle or by-pass of a turbine is cracked open and steam allowed to the condenser or to the atmosphere. The result of this method is distortion that seriously affects the running of the machine, by throwing the parts out of alignment. You will understand that the clearances in steam turbines are very small and the alignment must be almost perfect. In fact it is as nearly perfect as experts can make it.

The Correct Procedure

First, look to the oil. If you are depending on an oil pump separate from the machine for starting purposes you should first start the oil pump. If it is a condensing job we will assume that your condenser auxiliaries are going. You may have anywhere from 2 inches of vacuum to 10 inches before you start. Now you have the oil pump going and you note your oil pressure. (In some types the governor does not open or raise until the oil pressure is built up. This is a good thing, as you can't start the turbine without the oil pump.) When you have attended to this and you see that the oil is flowing properly, open the throttle out sufficient to start the machine quickly. Don't waste time at the throttle cracking it open, little by little, as the longer you take getting the turbine turning over the more harm you are doing. Open up promptly (two or three turns), if it is a machine of any size it will be draggy or tardy to start but once she moves off you must be ready to close your throttle down until it is just cracked off the seat as by the time you do this the turbine is revolving at anywhere from 100 to 300 r.p.m. and this is just about right for warming up. Now don't let your vacuum build up too fast, because with a high vacuum and no load the machine will come to speed quickly; this is not desirable. If the turbine is used for propulsion you will have load and it doesn't matter about the vacuum, that is you may build the vacuum right up and control the turbine from the throttle. Now with the turbine turning over at 200 or 300 r.p.m. you can let her warm up for anything from 10 minutes to 30 minutes depending upon the size. In the meantime look to your oil flow and if O.K. and the machine warmed you can now bring the machine to speed and this is where some turbines differ greatly in the manner of bringing them to speed without vibration. There are two critical speeds, that is, two speeds where they vibrate, one is below the normal running speed and one above the normal running speed. Now in coming to normal speed the machine must pass through the first critical speed, and at this point the vibration may be little or great, it depends upon the peculiarities of the type. If the machine is not properly carried over this point it will be necessary to shut down completely and start over again or run the machine in a vibrating condition that may be a long time quieting down. I have seen them vibrate more or less for 30 hours when put in in a hurry or unskilfully manoeuvred through the first critical speed. The proper way to do this can only be learned from practice. Some machines must be brought over the first critical speed quickly and steadily accelerated, probably the acceleration over the critical speed will be too great to allow it to continue up to normal, so after the machine has passed that speed you will be obliged to check the acceleration, as you mustn't let her on the governor too suddenly as this causes a sensitive governor to swing or hunt. I've seen them swing from dead closed to wide open and keep going that way until the throttle was partly closed and the result is lost time and probably a vibrating or rough running machine and a good chance to get a slug of water.

Some machines can be accelerated steadily from the warming up speed to full speed, but you should try every kink you know of to bring the machine into normal speed quietly before you decide that the balance is imperfect as 50 per cent. of the rough running turbines are thus because they are not properly warmed up and brought to speed as they should be.

Before going this far I should have mentioned that you should close your auxiliary oil pump down as soon as the speed of the turbine was sufficient to maintain normal oil pressure by the gear driven oil pump. The oil pressure also has a great deal to do with the quiet running of a turbine. If the oil pressure is too high or too low it will cause vibration. You will notice that the oil pressure may be several pounds too high, or higher than normal, when you first start up, but falls off when the oil warms up to running heat.

The oil pressure also falls off when the strainer gets dirty. You will usually notice vibration or a change in the sound of the machine when the oil pressure changes.

Small sizes of turbines are frequently ring oiling and some sizes up to 1,000 horsepower depend upon ring oiling only when starting up. That is there is no auxiliary pump. It is extremely important to get those machines away from rest rather quickly so that the rings will turn with the shaft. If you start the machine revolving slowly the rings may not turn and remembering that there is absolutely no oil under the shaft when the machine is first started the bearing lining will suffer more in ten minutes if the rings don't turn than in ten years of normal running under oil pressure, because under normal oil pressure the shaft does not touch the lining at all. I've seen linings that were in use for eight years that the scraper marks were to be seen as plain as if they were made an hour before.

Remember the Relief Valve

Now there is another important thing to remember, that is the relief valve on the turbine casing or on the condenser, and in stationary jobs usually situated in the atmospheric exhaust line near the condenser. This relief valve should never be neglected and no turbine should

be installed without a relief valve where there is any chance of obstructing the free exhaust. The reason is that the turbine casing is not built for internal pressure. It is only a thin shell of cast iron and should the free exhaust be obstructed the pressure will surely build up in the casing and blow it to pieces and I have known it to kill the engineer and wreck the engine room. This happened a few years ago. The engineer was closing the sluice valve from the turbine floor, standing beside the machine (a Curtis) carrying a light load. He intended to start up in the morning non-condensing and as the shift was about finished he was changing to non-condensing in order that everything would be set for the morning. The atmospheric valve did not open and the machine went up, killed the engineer and wrecked the plant.

In normal operation the pressure in a condensing steam turbine casing when the machine is fully loaded is less than, or at least not greater than, the atmosphere, in cases of momentary overload the pressure in the casing may be one or two pounds above atmospheric, in a non-condensing turbine the maximum may not exceed 5 to 10 pounds, and is usually less, but the non-condensing turbine casing is made stronger. Some turbines are of the bleeder type and are built to stand a pressure of probably 50 per cent. of the boiler pressure but those are special cases.

Now the difference between getting power from a steam engine and a turbine is this. In the former we get the power from the mean effective pressure on the piston and the engine cylinder is made strong enough to withstand the pressure so if the exhaust valve is closed off we can't blow the cylinder up, we will simply choke the engine off and she will stop.

In the latter case we get power from the turbine wheel by letting the steam impinge on the blades at a high velocity. The steam presure is greatly reduced in order to increase the velocity. Now a body (the steam) in motion has kinetic energy and this kinetic energy is given up to the wheel. Now if we close the sluice valve to the condenser and there is no relief valve we build up a pressure in the casing, the limit of the pressure we can build up is the boiler pressure.

A Turbine Explosion

There was only one case of turbine explosion that ever came directly to my notice, and how the engineer escaped alive is more than I could ever tell. It was a miracle. I viewed the wreck next morning and there was nothing left of the turbine casing except the sole-plate that it rested on. It happened this way. The night engineer was starting a 25 k.w. exciter set and some one throughout the day closed the exhaust valve when making other repairs. There was no relief valve and when the engineer turned the steam into the turbine the casing exploded. The engineer did not get hurt much but the exploded casing went in every direction.

I received another lesson about three years later that may interest engineers, in a stationary plant where we had turbines as well as engines, compressors and pumps. We had a good deal to look after and were running most of the time seven days a week and twenty-four hours a day and our turbines were the least of our troubles. In fact they were so satisfactory that we probably got careless of the turbines in our solicitude for the other apparatus that required constant attention, and of which we had no duplicates. We had then two large turbines and one small 150 horsepower stand-by for lighting, etc. One night the night engineer lost the vacuum on the turbine set, owing to unusually low water. The air pump was a Blake Knowles 20 inches by 12 inches air cylinder driven by a 10 inches by 12 inches steam engine. If you happen to know the Blake Knowles air pump you will know that the air valve is nothing more than a (D) valve with an extra port or by-pass, but the function is just the reverse of what the (D) valve performs in a steam chest. In order to let the air exhaust to the atmosphere there is a thin steel plate (feather valve) on the back of the main valve, seating against a grid when the air cylinder is taking a charge from the condenser, and opening outward when discharging the air.

When the engineer lost the vacuum the oiler happened to be in the basement oiling the air pump when all at once the engine began to run away. The oiler of course went to shut down, and showed his presence of mind by tripping the governor which was a trigger affair, but the engine went faster than ever and before the engineer of the watch had the sluice valve to the condenser closed the air pump was a wreck. Well, when I got the whole story next morning I couldn't tell which of them was lying, but I thought one of them was, but for the liking I had for the oiler and the faith I had in his honesty I'd have never found out what happened, because I had my mind made up that the oiler must have been walking in his sleep and poured oil on the governor belt and that they invented the yarn for me. However, after having another talk privately with the oiler I felt that he told me the truth, but what happened was to me a mystery for some time. We repaired the engine and I used to go down there sometimes and look at the layout and try to make it out. I was just about to let it go as an unsolved riddle, but when I am dead up against a thing I have a habit of sitting down and making a sketch of the layout, whatever it may be, and studying it out on paper. So this day I made a sketch of the air cylinder and valve and at once I could see it all. When the engineer lost the vacuum a pressure built up in the condenser before he got the sluice valve shut off. (It took five minutes to close one of those valves by hand.) The relief valve which was supposed to relieve at ½ pound was sticky and the machine full loaded. The pressure in the condenser must have been 8 or 10 pounds and the air pump cylinder became a steam cylinder with a D valve cutting off the steam. No control on the engine as the governor was useless. The air pipe from the condenser to the pump was now a steam pipe. The low pressure steam acting on the 20-inch air piston drove the engine to pieces in a few minutes. I knew very well that ½ pound pressure would not drive the engine over speed and investigated and found the relief valve sticking.

The Gland Packing

There is another thing that gives trouble or worry and that is the gland packing seal on the shaft. Very small sets are packed with fibrous packing and sometimes with semi-metallic packing, large sets are almost without exception packed with metallic or carbon rings that just clear the shaft. The rings are in sections and are arch bound so that they are held in place in a groove and together by a garter spring and all called the labyrinth type. The packing does not make an air-tight seal but the exclusion of air is accomplished by using steam or water to seal against air. When sealed with steam there is usually a reducing valve in the steam seal line to maintain a constant low pressure of about 10 pounds per square inch. The leakage along the shaft is drawn into the condenser and is available for make up feed water. If the amount of steam admitted to the seal box is not nicely regulated it will result in a cloud of steam blowing away from the turbine and a loss that must be made up to the feed supply, or if too little is admitted the result is a low vacuum.

With water seal there is not much trouble until the seal box is worn badly, when it can be removed. If the packing is good there will be little or no water get over to the condenser steam space, but when worn there will be a considerable amount. The action is as follows. The water admitted is given a revolving motion by the rotating shaft, which hurls a solid ring of water around at the same speed as the shaft. The friction of the water revolving against the stationary element is sufficient to heat it to the vaporization point in a short time, unless a certain amount is being continually supplied. In order that the centrifugal force will not force the water entirely out of the gland the discharge is carried up about 20 feet so that there will always be a head of about 10 pounds to be pumped against (you may consider the revolving shaft inside the seal box as a rotary pump).

In small sets where fibrous packing is used there is sometimes an attempt made to lubricate the shaft, with vary-

ing degrees of success, and in some cases none whatever. The packing should bear as lightly as possible on the shaft since it will cut the shaft in a short time and besides if it tends to grip the shaft it will cause vibration and any unevenness in the packing or the gland will cause misalignment of the revolving element.

End Play

The end play is adjusted by shims or a geared nut that is advanced or backed up by a worm. The end play varies in some machines but the total end motion is between 11 and 22 thousands with the average in moderate sizes about 10 thousands. This end motion is divided after the machine is assembled, that is when the motor is revolving it is advanced toward the stationary blading until it just rubs, then brought back until it again touches. The total movement is marked and divided, for example if the total movement is 16-1000 the thrust bearing is locked where the clearance is 8-1000 each side of the revolving blades. The clearance between the casing and the perimeter of the wheel is somewhat greater and is greater in large sizes than small sizes, on account of the greater distortion due to temperature.

There is a very great temperature range from the high stage of large sets to the last or low pressure stage. The temperature at the turbine inlet is that corresponding to superheated steam, and in the last stage that corresponding to a high vacuum. Thus there are in large sizes that are not compounded severe strains and distortions in both the revolving and the stationary elements. It would appear that compounding of large sets has to some extent eliminated or at least simplified those stresses and the clearances can be adjusted closer than if in one large unit expanding the steam from the initial pressure down to the condenser pressure.

Emergency Governor

The emergency governors of all steam turbines are fundamentally the same, though differing in construction details. The throttle has on its stem a sliding sleeve that is engaged by a trigger or pawl which is connected through links to another pawl, mounted on the front bearing, an eccentric ring, or a plug (depending on the maker's particular construction), is so attached to the revolving shaft that it revolves with it. It is held in toward the shaft center by a spring. The spring tension is so adjusted by trial that at normal speed of the machine the trip just clears the pawl or trigger, but when the speed is increased about 8 per cent. over normal the centrifugal force overpowers the opposing spring and the ring or plug projects from the revolving shaft and trips the pawl, which in turn disengages the sliding sleeve and the unbalanced pressure on the throttle causes it to close instantly closing the machine down. There are various forms of construction but this description wil assist the engineer to follow out the important details of the particular kind he may have under consideration, bearing in mind that in all cases the centrifugal force of a revolving weight must overpower some other force in order to trip the emergency, and the opposing force is usually an adjustable spring. Great care must be taken that the connecting links from the throttle to the emergency trip do not bind or that the knuckles and joints do not become clogged up with dirt or paint. It is better to keep them bright and the throttle packing gland should never be too tightly packed, as this may cause it to bind.

The turbine should be allowed to over speed occasionally when not loaded in order to make sure that the emergency will trip and close the machine down. This can be done by holding the governor and observing the tachometer or speed indicator. The emergency should work at 8 or 10 per cent. above normal. If it does not it is not advisable to allow the speed to go much higher. I would say 14 per cent. would be the limit, as the second critical speed may not be far from this value and the machine might go to pieces. Of course, it might not do so, but that is too uncertain. It is just like letting your boiler pressure go above the safe working pressure. It might blow up or might not.

ROLLING MILL ENGINE

What is claimed to be the most powerful rolling mill engine in the world is now in course of erection in a British steel works. It is intended to drive a train of 32-inch finishing rolls for large sections of steel. Some idea of the enormous size of the engine may be gained from the fact that the face of a man standing on the ground just comes to a level with the crank shaft—the engine being a vertical one. The maximum horse power developed is 25,000 at a speed of 140 revolutions per minute. There are three cylinders, each 45 inches in diameter, and with a stroke of 52 inches. Joists up to 24 inches deep and 12 inches wide will be rolled in this mill. The makers have given a guarantee that this huge engine will be capable of reversing four times in one minute, and they are confident that the engine will do better than the guarantee. This rapidity of reversal, which is of great value in increasing output, is secured by a most ingenious system of valve gears. The engine is carried on a massive concrete foundation with an iron casting two feet deep—weighing over 100 tons—embedded in it. Small auxiliary engines are used to operate the reversing gear, also the stop valves.

CANADA'S COAL SITUATION

Canada created a record for coal production in 1920, when she produced 16,968,658 short tons, as against 13,919,096 short tons in the preceding year, or an increase of 21.9 per cent. The previous high mark was set in 1913, when the output totalled 15,532,878 short tons. Exports increased to 2,558,223 tons, as compared with 2,070,050, but this was counter-balanced by the increase in imports from the United States from 16,982,773 to 20,815,596. The total value of production is estimated at about $70,000,000.

With only one exception, that of Saskatchewan, every province of the Dominion exhibited an increase in production during the year over the 1919 figures. A particularly interesting feature of the year was the wresting from Nova Scotia by Alberta of the honor of premier producer, the Western province leading the Eastern by nearly four per cent. Alberta produced 41 per cent. of the total output, or roughly 6,700,000 tons; Nova Scotia, 37.8 per cent., or 6,500,000; British Columbia, 18.3 per cent. or 2,550,000 tons; Saskatchewan, 1.9 per cent., or 330,000 tons; and New Brunswick, 1 per cent., or 170,000 tons. The reduction in Saskatchewan's output is attributed to the greatly increased use of Alberta coal in Manitoba and that province.

A both interesting and gratifying feature of the coal situation in 1920 was the increased use of native coal, especially in the Prairie Provinces. The war, which cut down shipments of anthracite from the United States to Manitoba, gave Alberta her opportunity to introduce her product on the qualities of which there was a lack of education. She was not slow to force her way, and is maintaining the position assumed with every indication of increasing her market. This is shown very clearly in the shipments of coal from Alberta eastward, which in 1920 totalled about 500,000 tons as compared with approximately 250,000 tons in 1919.

TESTING ENGINE CRANK SHAFTS

When an engine is built, one of the items to be tested is whether the crank shaft is in strict alignment; and in order to ensure the satisfactory running of the engine, tests with a similar object should be made periodically. A British engineering firm recently introduced a new instrument for making such tests accurately and rapidly. It consists of a dial divided into thousandths of an inch and a pointer actuated by a plunger which juts out at the top of the dial. Flanking this plunger are two spring plungers; the dial is carried on a column which screws into a base. The apparatus is used—in a manner which cannot be described without technical details—to measure the distance between the inner faces of the crank balance weights or of the outer ends of the crank webs, first when the shaft is in one position and next when it has been moved through half a revolution. If the pointer shows a movement to one side or the other it proves that the alignment is not perfect. This instrument is made either non-adjustable, for only one size of crank shaft, or adjustable for any sizes in which the distance between the web is not less than 4½ inches or more than 9½ inches. It can be used for either horizontal or vertical engines.

Overhauling and Adjusting in the Engine Room

The Importance of Keeping Things in Their Proper Place, and Having a Place to Keep Them—Have Proper Spanners for Awkward Places—How to Overhaul a Pump

By "FITTER"

WHEN the young man who is starting in to become a first class stationary engineer graduates from the boiler room to the engine room in the ordinary course, he has a lot to learn. One of the principal things he must become acquainted with is the overhauling and adjusting of the main driving units as well as the auxiliaries. He will at first get only such jobs as packing glands, pistons of pumps, renewing valves in the water ends, etc., but the time will come when he will have to tackle bigger jobs. He will at first be under instructions from some more experienced man, or perhaps be just assisting such a man, and if he knows something about the methods employed by those who are old at the game, it will prove a help to him in his progress towards the top.

There is never any lack of work in an engine room, even if it consists of only a single cylinder non-condensing engine driving the factory through a belt. There will be no lack of work here, because there will usually only be one man to do all the work there is. Similarly, as the plants get larger, there will still be about the same amount of work to each man, so that one does not have to look around very much for jobs that require attending to.

A Place for Everything.

One of the first things the young engineer should learn is to have the necessary tools for each job handy to that job, and if the same tools are used for several different jobs, to have them in a convenient place, and to see that they are put back immediately after being used, and not allowed to kick around until they are lost. There is real pleasure in doing a job if the tools are ready to hand, and do not have to be hunted for before the job can be started. When they can't be found, and makeshifts are pressed into place, the job is only half done, and every one is dissatisfied. It has been my experience that this is one of the great faults met with in many men in the stationary engineering line, and it is a very bad one. In every engine room that good old motto should be painted or engraved in plain sight of all hands, "A place for everything, and everything in its place."

Every piece of machinery in the engine room, when originally sent out from the factory, had its own spanners and wrenches accompanying it, made especially to fit the nuts made by the maker, and very often if not invariably made in special shapes to fit special awkward corners. Into how many plants of two or three years of age can one go, and find the original spanners and wrenches that went out with the job? Very few, it is to be feared. On the other hand, I have seen ships of ten times that many years' service, with all the original spanners that were in them when they were built. It is just as easy and easier to do this ashore as afloat, if the same interest and care is taken in the job.

If the original spanners have been lost, the next best thing is to get others made, as experience dictates will be the most suitable for the particular purpose. It is rarely that a spanner cannot be made to fit the most awkward nuts, and kept in a rack over the particular pump, air compressor or engine that it is meant for, or if not there in the store room in a special rack. Spanner racks are easily made from a piece of angle iron and fastened on the wall or the frame of the machine itself. This applies very particularly to those special wrenches for removing the studs of the water valves in pumps, which seem in many engine rooms to be always missing when required.

We will suppose for the purpose of getting a start, that the water end of an ordinary duplex pump is to be examined, to ascertain the cause of the pump not performing its duty properly. The first place one would examine would naturally be the valves, and these would be in some types of pumps easily got at through the hand holds, while in others it will be necessary to remove the discharge valve cover entirely. In either case nuts will have to be removed, and here is a place where a good habit can be formed. That is to always string nuts as they are taken off on a piece of wire or string in such a way that they can be placed back on the same studs or bolts from which they were removed. Careful observance of this habit will reduce the time required in trying to force bad fitting nuts on to threads they don't want to go on. If the nuts are strung, then the last nut to go on the string will be the first nut to be replaced on the last stud, and the opposite way round will be used when placing the nuts back. Besides this, the facts of having the nuts on a wire or string will prevent them slipping down into the pump or under the engine room floor, where they can't be found when the job is finished. It takes a little time perhaps to have the wire or string ready, but it saves a great deal more time in the long run. How often does it happen that a job is all fixed up and ready to be put in service again, while all hands are scurrying around to find a nut to fit, the original nut having mysteriously disappeared. When the nut is found, it is a different size over the flats to the nut on the job, and that abomination of any real mechanic, the monkey wrench, is brought into play. It has always been a source of wonder to the writer that a tool so essentially awkward could ever attain the popularity it seems to enjoy. The number of barked and bruised knuckles it is responsible for must be enormous, to say nothing of the nuts it has spoiled by slipping round the edge. It is a good enough tool perhaps for the boy who owns a bicycle, or a pair of roller skates, or for the carpenter who is handy at doing odd jobs, but in an engine room it is not the right kind of tool.

The usual duplex pump is fitted with hard or soft rubber valves, held in place by a stud with a hexagonal top, which forms a washer for the spring to work against. The chief difficulty encountered with the valves is that of the valves themselves breaking, the studs breaking off, coming loose in the seat or the springs breaking. The length of time they will last depends a good deal on the care expended when putting them in. First of all the springs used should be of the right gauge of wire and of the same number of coils as the original springs, or very closely approximating them. A spring with too much tension produces undue wear on the valves, and too light a spring allows too much lift and shock producing the same effect. Frequently the brass studs which were supplied with the pump are replaced by ordinary iron studs or bolts with washers to keep the spring in place. This results in the spring being misplaced after a very short time of working, and the valve soon shows signs of uneven wear. Putting in valves with too large a hole for the stud results again in the valves playing about the seats, the hole speedily becoming oval, and the life of the valve being shortened. If the thread in the seat appears to be worn, tap it out a larger size and get a special stud made to fit it. Do not put a stud in that fits loosely in the seat, as that means that you will have to open up the pump in a very short time. If the valves are good on one side, they can be turned over and used again, and if they are broken round the edges it may be possible by trimming them to use them again in a smaller pump. Remember that engine room supplies are expensive, and the more wear you can get out of material, the cheaper you are furnishing power.

If it is necessary for any reason to

remove the discharge valve chest cover, to reach the suction valve deck, and if this deck is also lifted for any reason, pay particular attention when replacing them to making a good joint between the suction valve deck and the body of the pump, as if there is any opening here the pump will draw air, and lose its efficiency. If the joint on the discharge valve side is bad you will be made aware of it by the water spurting out. If the faces of the castings are clean, a good joint can be made with a piece of flat lamp wick rubbed in tallow. Wool yarn, such as is used in siphons, wound round inside the studs will also serve the purpose, and is much easier to make and cheaper than using a rubber gasket. If rubber is used the upper surface nearest the cover should be well rubbed with graphite, so that when the cover is lifted, it will come away freely from the joint, and leave the rubber sticking to the suction valve deck. Making a rubber joint to cover the whole face inside and outside the studs on a big pump is a waste of rubber, because the part outside the studs is merely waste material. When tightening down the cover, go very carefully, tightening down the nuts in the centre a little first, following with the nuts at each corner a little at a time until the cover is down absolutely square all over. You can then tighten up by going all round one nut after the other, not putting too much tension on any one of them till they are all firmly embedded. Then go round them again and give them the final tightening. If the nuts have been all evenly treated, there will be not very much more to be got on them at the final round. Don't make the mistake of trying to see how hard the nuts can be pulled. There is no need for it, and you are only straining both yourself and the pump for nothing. Remember there are usually enough nuts on the cover to get the requisite tightness without undue strain, and if the joint is leaking after the ordinary tightening, it is best to remove the cover and see if there is a piece of dirt in one spot, or the joint has been broken in placing the cover on. If the joint is not properly laid on, you can tighten until you break something without stopping the leak altogether. Remember in all overhauling work, to refrain from making it a test of strength. Engineering appliances are made to fit, and do not need to be forced except in a few cases.

There doesn't seem to be a great deal about replacing a valve in a pump, but it has to be done properly, unless it is going to require replacing again in a very short time. This means that the valve must be a good working fit on the stud, neither slack nor tight. The stud must be of the proper length, a good fit in the thread of the seat, and not depending on the last turn to make it tight. The spring should fit under the hexagon head of the stud and on the shoulder made on the stud to receive it, so that it will be kept vertical and thus prevent the valve from coming down on the seat unevenly. The spring itself should be the right size wire and the right number of coils and not just any kind of a spring that happens along. The seats should be examined to see if they are true, and if found to be warped or worn, the easiest way is to take them whole deck out and face them up to a surface board on the bench. If there is a machine shop in the factory, get them to put the deck with the valves in on to shaper or a miller and take a light skim over them, which will bring them down even. If the valves themselves are brass instead of rubber, they can then be faced individually each to its own seat.

There is another point to watch in regard to the seats. Sometimes the seats wear until they are just a little lower than the casting they are held in, and if the valve is the least bit larger than the seat in diameter, it is held up by the casting and, therefore, is kept open. This point should be carefully watched, as it not infrequently causes trouble, and is not always immediately obvious when looking for the cause.

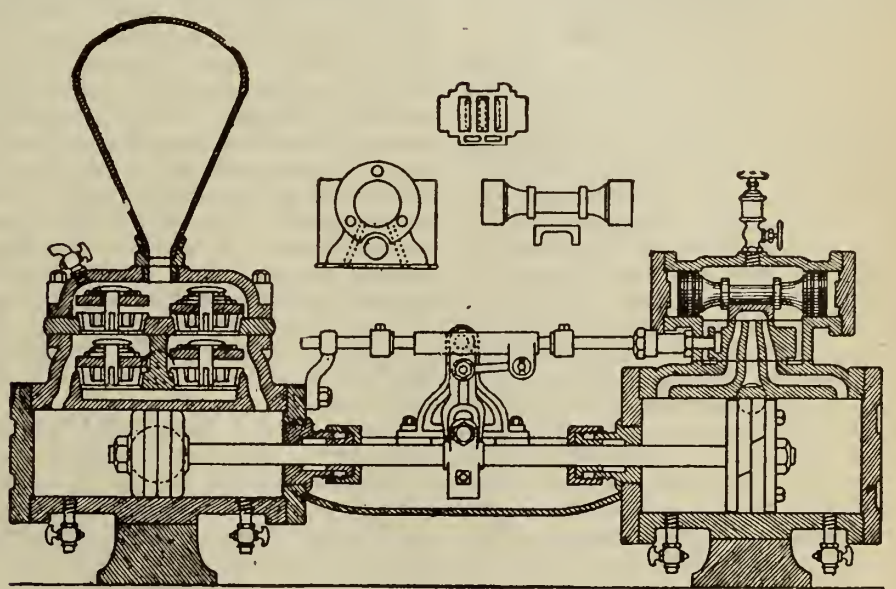
The Valve Seats.

Valve seats are usually screwed into the castings, on the duplex type of pump, and lugs are provided inside the seats to enable them to be screwed out with a special wrench. The threads are usually tapered like a pipe thread, and it is usually a matter of great difficulty to get them started if it is wished to take them out. In some cases valve seats are driven in to the casting and in these cases it is sometimes the practice to fit a set screw to prevent them working loose. It is easy to remove this type of seat by simply placing a plate across the bottom of the seat, and pasing a bolt through to the top passing through a plate laid over the opening. The nut is then screwed down on the top plate, pulling the bottom plate and seat up with it.

The only time it is necessary to remove a screwed seat is when it gets so badly worn that it is not possible to do any more with it. It is not going to be used again, and the quickest and best way to remove it is to take a fine cross cut chisel and split down one side of the seat, after which it can be easily turned out. If it is desired to save it for any reason it will not do to use this method, but it has been my experience that when a seat of this type is removed there is no intention of putting it back and it saves time to cut it rather than try and turn it out. Of course, care must be taken that the chisel does not damage the thread of the casting or it will be difficult to make the new seat a tight fit. A little care will ensure this does not happen. When putting the new seat in, it should be made a good fit all the way in, and not slack two-thirds of the way and tightened up at the last. If you do not have spare seats on hand from the makers of the pumps, or they cannot supply them, let the machinist who is going to make the seats get his size from the casting, so that he can make a good fit.

It is not very often that new seats are required under ordinary circumstances, so that when they do have to be fitted, fit them so that they will last at least as long as the original ones.

(To be continued.)



SECTIONAL ELEVATION OF TYPICAL PUMP.

BULLETIN

The Yarnall-Waring Co., Philadelphia, have issued a new bulletin, No. R-1401, describing their Yarway Balanced Control Valve. This valve has been designed in the first place for use with the Yarway Lea V Notch Recording Meter which was described in these pages recently. The valve is of the double disc and seat construction, the valves being guided by wings. Renewable discs and seats are fitted. The operation is controlled by a float and lever.

Using Pulverised Coal in Central Station

Extract From a Paper Read by John Anderson, Chief Engineer of Power Plants Milwaukee Electric Railway and Light Co. and Dealing With Experience at The Oneida Street Station, Milwaukee

COAL in finely ground or pulverized form was first used successfully twenty-five or thirty years ago in the manufacture of cement. In this application its economy was quickly recognized and to the advantages it possesses in burning cement may be attributed the present high state of development to which equipment for pulverizing coal has already been brought. From this beginning its uses have broadened until now pulverized fuel serves to heat furnaces in numerous and diversified industries. Up to within a few years ago its use was most advantageous in those furnaces that operate under a slight pressure for the purpose of excluding air when the doors are opened and wherein a low velocity of gas travel is desired—typical requirements of furnaces in the cement, copper, and iron industries. For these special and for similar reasons, pulverized fuel found its greatest use in annealing and forging furnaces; in cement and lime kilns; in the manufacture of refractories and substances that require drying or burning; and in surface treatment of many metals.

However, with the recent heavy increases in price of coal any process which promised greater efficiency found a broad field opened up before it for application to stationary boilers. Previous to this time some work had been done in developing its use in locomotives, but the reasons for its application to stationary boiler furnaces, and the small saving that might be effected with coal at a low price did not promise to offset the cost of pulverization. Such conditions did not encourage the use of fuel in powdered form therefore until the higher prices of the last three years forced economy in every direction.

It is the purpose of this article to describe the pulverized coal fired furnace only as applied to the steam boiler excluding locomotive practice, to point out its advantages in such use and to state the economies effected thereby.

Pulverising

The use of pulverized fuel in any industry necessitates a special plant for preparing the coal. It is the cost of installing and operating this plant which will always determine the advisability of adopting powdered coal for steam generation in any one location. In such a plant there must be equipment to separate trampiron from the coal, to crush it to a size suitable for drying and feeding to the pulverizers, to remove the moisture and to finally grind it to the desired fineness.

As the coal is received at the plant in the form it left the mines, it is necessary to pass it over a magnetic separator which removes all trampiron, such as bolts, nuts, pick-points, etc., thus seving as a safeguard against damage to the pulverizing and conveying machinery. A crusher must be used to reduce the green coal to a size suitable for proper drying and pulverizing, unless coal can be procured in sizes less than ½-inch screening without sacrificing heat value which is usually at its lowest in smallest size screenings.

The fuel is next dried. The object in drying the coal is to bring it to a condition in which it can most easily be pulverized and most uniformly controlled by feeders into furnaces. In a pulverized coal fired furnace, most uniform temperature conditions are obtained with dry coal. Moisture in varying or large quantities in pulverized fuel definitely prevents a regular controllable flow of mixed fuel and air to the burners. For the removal of moisture a mechanical dryer, which reduces the water content of the fuel to about one or two per cent., is installed. This dryer usually consists of a double rotating cylinder, so arranged that hot gases from a small furnace are passed through the coal as it travels by gravity through the shell of the dryer and is delivered to the pulverizers.

The dried coal is next fed into the pulverizers. The fuel is ground to an impalpable powder, varying in fineness from 80 per cent. to 85 per cent. through a 200-mesh screen. This process completes the preparation cycle and the coal in this form, after being conveyed to storage bunkers adjacent to furnaces, is ready for firing.

Dust Collecting

Dust collecting and reclaiming equipment, although only auxiliary to the drying and pulverizing machinery, is of great importance in the most economical, as well as the cleanest operation of a preparation plant.

The cost per ton of preparing coal depends upon the size of the plant and the quantity of fuel handled, but ordinarily will vary between the limits of twenty-five and fifty cents. It seems that a great deal of work toward reducing this cost remains to be done, especially along lines of utilizing waste gases for drying, in plants not provided with economizers. Development of a furnace design which will allow of burning a large percentage of finely divided coal, but capable of taking care of a smaller amount of larger sized particles, presents further study along this line. This is possible in view of the fact that the pulverizers consume about 86 per cent. of the total electric energy required for all moving parts of the coal preparation equipment. Both of the items mentioned above, if capable of being reduced as suggested, will also cause a reduction in the cost of the pulverizing department labor.

Continuous and uniform operation of the pulverizing division of a plant is dependent largely upon the ability of the operators to recognize and meet the varying properties of the coal as it arrives. Dryer operation especially must be changed frequently so as to handle varying sizes of coal (from high percentages of dust to high percentages of small nut) and varying amounts of moisture, both inherent and surface, and yet supply continuously a coal of uniformly low moisture. Irregularities in the drying process usually manifest themselves throughout the entire coal cycle, and very often with the result that the fuel feeding system becomes plugged at points most readily affected by wet coal.

Little need be said concerning the equipment which feeds the fuel to the furnaces. Feeder screws (*1) driven by variable speed motors carry the fuel from the storage bins to the air mixing chambers from which it is blown as a mixture through pipes to the burners and then into the furnaces. Air additional to that used for carrying the fuel into the furnace is taken through auxiliary inlets, located in the furnace front, and can be varied in amount by manipulation of the stack damper, which serves to change the gas velocities through the boiler and thus the volume taken into the furnace. With coal and air supplies easily adjustable, perfect fire control is assured and it becomes at once obvious why coal is burned so efficiently in pulverized form.

Combustion Conditions

In further explanation of this it is well to consider briefly the indications of efficient combustion applied to the steam boiler. Chief among these is the percentage of carbon dioxide, or CO_2—the product of complete combustion—which is found in flue gases. Next in importance is the percentage of carbon monoxide, CO—a product of incomplete combustion—which may be found at the same time.

*1 Note—The feeder motor controls at the Oneida Street Plant are all provided with cutout and if at any time the air blast to the mixing chambers and burners is lost due to a blower shut down all coal feeders are automatically stopped thereby preventing serious plugging with attendant interruption to operation of boilers for what could easily be a considerable period.

The condition desirable is that with the percentage of CO_2 as high as practicable there should be no CO—a condition obtainable to a greater degree in a pulverized fuel furnace than in any other type. Complete combustion with the least amount of excess air requires the best distribution of that air and the problem of furnace efficiency therefore resolves itself mainly into one of air supply, not to the furnace alone, but to each particle of coal. With a fuel finely pulverized, air can be made at once available to each particle since the surface exposed to air is increased many times that of a lump and combustion is rapid, complete and efficient. With fuel in lump form air must be supplied through a bed, the outer surface of the lumps must be burned off, the process of combustion eating into the lumps slowly and as a result combustion is often gradual and unequal—where the fire is thin too much air is passed; where it is heavy there is too little air. To insure complete combustion in any furnace some excess air must therefore be provided. The use of pulverized fuel reduces this excess to a minimum, gives a higher and more uniform percentage of CO_2 and therefore a higher and more uniform efficiency.

The percentage of CO_2 to be maintained in pulverized fuel practice is determined to a great degree by furnace limitations rather than combustion consideration. From 16 to 17 per cent. CO_2 in the flue gases is easily obtainable but it cannot be maintained in actual operation due to exceedingly high flame temperatures that result and the consequent destruction of the brick work. The temperature of the furnace therefore must be regulated by varying the volume of excess air. The temperature of the flame should not be above 3,000 degrees F. and that of the brick work in the flame zone not more than 2,400 or 2,500 degrees F. Higher temperatures than these usually result in fusion of the ash particles and formation of a molten slag which is very destructive to the brick work with which it comes in contact.

In attempting to carry combustion conditions of a furnace so as to obtain exceedingly high percentages of CO_2 usually too little attention is given to the losses resulting from the formation of carbon monoxide or CO. Carbon monoxide, a highly combustible gas, is formed when the excess air admitted to the furnace is insufficient to properly surround and completely oxidize all the coal particles. Heat losses occurring when carbon monoxide is present in the gases of combustion, outweigh any gains that may be effected by an exceedingly high CO_2 and are always to be avoided.

Wide Variations of Quality

In the discussion of furnace efficiencies consideration should be given to the adaptability of a pulverized fuel fired furnace to the use of widely varying grades of coal without resultant losses in economy. Further, boiler capacity, even under heavy overloads, is in no way affected when an inferior quality of coal is burned. It is known that the combined efficiency of a boiler and furnace does not decrease when the fuel is poor, which condition does not hold true for the stoker. In the case of the stoker, the dropping off in efficiency is at a more rapid rate than the B.t.u. value of the fuel would indicate as normal, and so much so, that the point is rapidly reached when proper combustion cannot be maintained.

Operation of a pulverized fuel fired boiler, equipped with proper instruments, can be varied to take big fluctuations in load over very brief periods of time. A heavy overload can be quickly taken on or dropped off by adjustment of the coal and air feeds, and without any waste of fuel as always occurs under like conditions in stoker practice. No losses occur due to clinkering of coal or cleaning of fires, this condition of operation being entirely eliminated. Irregularities caused by change in quality and variation in size of coal, such as the fireman cannot successfully cope with on stokers, are also eliminated. Furnace conditions necessary to most economical combustion are more perfectly obtained and hence a horizontal combined efficiency curve is possible of approximate attainment.

Due to its easily regulated coal and air supply and its perfectly controlled rate of combustion, the pulverized fuel furnace practically eliminates losses of combustible in ash. Ordinarily this loss is relatively large and varies according to the nature of the coal, type of stoker and the boiler load carried. In pulverized fuel practice the loss is very small and these variations do not occur.

The ease with which the fuel feed and draft is controlled, the ability to take on and drop off heavy overloads in a brief time, the thorough combustion of the coal and the uniformly high efficiency obtainable under normal operation constitute the chief advantages of pulverized fuel over other methods of coal burning.

An additional economy is effected during banked boiler hours. Banking conditions when operating with pulverized fuel are somewhat different than those obtained in stoker practice. By stopping the fuel supply and closing up all dampers and auxiliary air inlets, a boiler fitted for use of pulverized fuel can be held up to pressure for several hours. The furnace brick work having been heated to incandescence during operation gives off a radiant heat which is almost all absorbed by the boiler rather than escaping up the stack intermixed with an excess of cooling air. Radiation losses only occur as against radiation plus stack and grate losses in the case of the stoker.

Maintenance Features

Commenting for a moment on the maintenance features of such a plant as has been described it is the writer's belief, based on two years' operating experience, that the furnace brick work in a pulverized fuel furnace will stand up equally as well as a stoker installation, with a very great advantage in favor of the former due to the elimination of all iron work in the furnace or anywhere near the high temperature zones of the boiler furnace. Regarding the maintenance of the pulverizing plant equipment it has not been found that any great amount of maintenance is likely to be necessary as all the equipment is of the slow moving type and many opportunities are afforded of applying the same concentration of effort that has been typical of the stationary engineer's work in improving equipment when defects or fast wearing parts are uncovered. The pulverized machinery manufacturers have done a great deal along this line, but there are still matters that can be improved upon by the engineer looking for the least troublesome as well as most economical plant from a maintenance standpoint.

Powdered fuel installations are not feasible in every location. There is one limitation and that is the size of boiler plant to be served. A plant of less than 2,500 developed boiler horsepower on a twenty-four-hour operating basis should not consider using powdered fuel. The amount of coal pulverized per day, the cost of installation, and the labor for operating preparation plant, when properly studied, will bring before those interested the reasons therefor.

In general, we have found the powdered fuel method applied to our furnaces a distinctly advantageous one. Our firemen prefer to operate such equipment rather than the stokers when it becomes a matter of choice. It has proved more economical as evidenced by the monthly coal bill. It seems to make the formation of scale in the boiler less than in stoker fired boilers. There is absolutely no trouble from smoke, consequently no reduction in ability of boiler to absorb heat due to soot on tubes.

The use of high sulphur coal which is so destructive to boiler tubes, breechings, smoke stack, and all other steel equipment found in a boiler plant is much more satisfactory as the low moisture content of coal as fired reduces the opportunity for attack from sulphuric acid.

Danger of Explosion

Although frequently cautioned against explosions, we have had no evidence that such caution is necessary. The reason for our freedom from such unpleasant occurrences is due almost entirely to a proper care in preventing coal from being dried too much and pulverized to a fineness beyond what is necessary. Matters of a kind similar to the fore-

(Continued on page 33)

Hazards from Coal Dust in Industrial Plants

Tests of Explosions—Fires in Storage and Bins—Some Suggestions—Danger From Backfires—Results of the Investigation by the U. S. Bureau of Mines

SINCE the introduction of pulverized coal as a substitute fuel for natural gas in various types of heating furnaces used in steel mills, a number of fires and explosions have occurred, resulting in the loss of life and property.

As one of the primary functions of the Bureau of Mines is to conduct investigations in the utilization of mineral substances with a view to increasing safety in the use thereof, it was deemed advisable to investigate the hazards involved in the industrial use of pulverized coal and, if possible, to devise methods of preventing future accidents arising therefrom. The knowledge of the explosive qualities of coal dust which the Bureau has gained in studies affecting dust explosions in coal mines was of material assistance in these investigations.

Several plants were visited in which either fires or explosions had occurred, and data obtained as to the probable cause of the accidents.

There was found to exist, among some of those employed about the furnaces, a lack of knowledge of the explosive and inflammable qualities of powdered coal.

A small stream of pulverized coal leaking down from a defective joint in a coal transport line did not attract much attention, whereas, had a leak in a natural gas line occurred under similar circumstances, no doubt it would have had immediate attention.

As a matter of fact, if by any means the dust cloud should come in contact with an open flame or hot metal, the effects would be as disastrous as if it had been gas.

This is exceedingly well illustrated by an accident which came to the writer's attention. In the system used at this particular plant, the pulverized coal is transported to the furnace through compressed-air lines. The fuel is fed from a storage bin to a blowing tank in quantities as desired, after which compressed air is admitted and the powdered coal blown to the furnaces. At the time of the accident some repairs were being made to the tank, and it was supposed that the air pressure had been entirely released as the pressure gauge stood at zero. There was, however, one or two pounds air pressure remaining and when one of the connections was taken off, a cloud of dust was blown across the room, 30 or 40 feet, towards the drier furnace where it came in contact with some live coals. Immediately the entire room was filled with flame which rolled back and forth over a space 60 feet or so in length.

It would seem desirable, as regards safety, if the management of all industrial plants in which pulverized coal is used for fuel, and especially of those plants in which heating and annealing furnaces are installed, would impress upon their employees the fact that clouds of fine coal dust are as dangerous as a body of unconfined natural gas, if the dust is liberated in close proximity to an open flame or mass of red-hot material.

Tests of Explosions

In the tests made of coal-dust explosions in the experimental mine of the Bureau of Mines, pressures as high as 130 pounds per square inch have been recorded, such high pressures are however, obtained only when the explosion has traversed some distance through the confined passageways of the mine. A somewhat analogous condition might be noted in an instance which came under the writer's observation. Coal dust was undoubtedly ignited in a pulverized-coal transport-line of spiral riveted pipe quite some distance from the fan furnishing the propelling air current. The pipe line confined the explosion until it reached the fan, when the cast-iron casing was completely shattered. Experiments have also demonstrated the fact that a mixture of 30 per cent. pulverized coal dust and 70 per cent. of finely powdered shale is explosive. These tests are applicable to the conditions that may be found in industrial plants, as they serve to show that the coal dust which may have settled on the floors and girders of the building is not necessarily rendered inert by the incombustible matter with which it may have become mixed.

Analysis of dust collected from the interior of mill buildings in which are situated furnaces using pulverized coal have shown that the dust sometimes contains as high as 23½ per cent. of volatile matter, only a little lower than pure Pittsburgh coal.

Fires in Storage and Bins

One of the most serious troubles with which users of pulverized coal have had to contend has been the number of fires in the storage bins for pulverized coal. It has been somewhat difficult to determine the exact cause of these fires, but undoubtedly spontaneous combusion has played an important part in the origin of some of them.

It is obvious that coal when finely powdered presents a much larger surface and a much larger quantity of coal to contact with oxygen than when in solid masses.

In tests by Parr and Kresssman ("The Spontaneous Combustion of Coal" by S. W. Parr and F. W. Kressman, Univ. Ill., Bull. 46, p. 71) it was learned that "The rate of absorption of oxygen increases so greatly with the rise of temperature that the warming of coal by a steam pipe or boiler may enormously shorten the time necessary for spontaneous combustion or render spontaneous combustion possible in cases where it would other wise be impossible."

Experiments by Porter and Ralston of the Bureau of Mines ("A Study of the Oxidation of Coal" by H. C. Porter and O. C. Ralston, Bureau of Mines Tech. Paper, 65, p. 13) have also determined that the rate of oxidation of coal increases rapidly as the temperature increases.

The attached chart shows the rate of oxidation of Illinois coal (ground to the fineness of 80 to 100 mesh) at different temperatures. It will be noted that at a temperature of about 150° F. the rate of oxidation is very rapid.

In experiments by Threllfall ("The Spontaneous Heating of Coal" by Richard Threllfall, Jour. Soc. Chem. Ind., vol. 28, pp. 759-773) in England on the spontaneous heating of coal, the point at which the temperature of the coal began to rise very rapidly was found to be about 150° F.

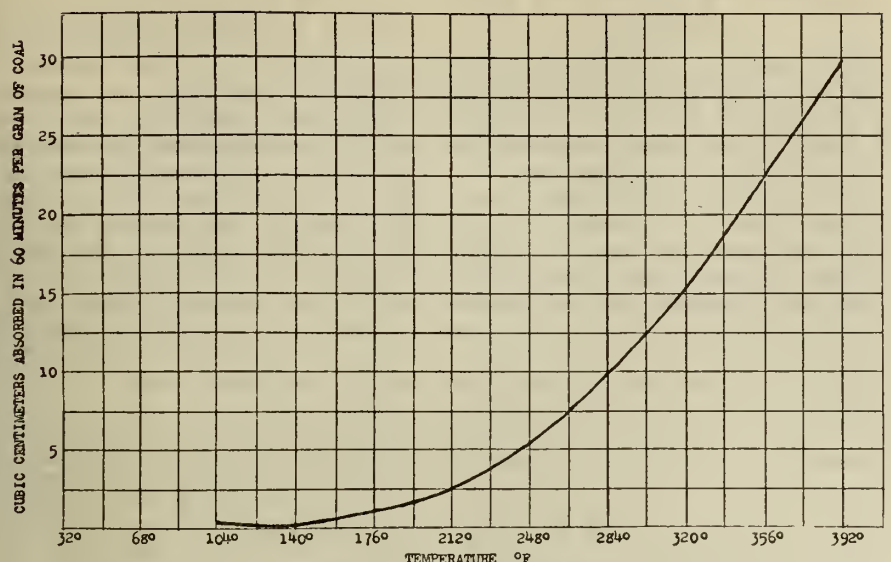
As the amount of heat generated in coal is in proportion to the amount of oxygen absorbed, from the above-mentioned expriments it is reasonable to assume that if enough air is present pulverized coal when delivered to a storage bin at a fairly high temperature, will in a short time approach the point of ignition.

In some of the systems used in drying and pulverizing coal, the fine coal, about 90 per cent. of which will pass through a 100-mesh screen and 70 per cent. through a 200-mesh screen, is delivered to the storage bins at a temperature of 125° to 130° F. It is possible, however, for the person running the drier to permit the fire to become hotter than normal and thus overheat the coal in the drier. Such an instance has been brought to the attention of the Bureau. In this case a pyrometer placed in the end of the drier normally registered a temperature of 150° F., but at the time of the explosion in the pulverizing house, a temperature of 350° F. was registered.

Where the drier becomes overheated, the coal may be delivered to the storage bins at a temperature at or above 150° F. If left in the bin for a comparatively short time, it is very probable that the temperature of the coal will rise to such a point that when mixed with air the coal will burn rapidly.

Overheating of the coal is especially liable to happen in the type of drier commonly known as "direct heat" drier, in which the gases from the combustion chamber pass directly through the center of the drum and come in contact with the coal passing through. Particularly

FIGURE 1.-- CHART SHOWING RATE OF OXIDATION OF ILLINOIS COAL AT DIFFERENT TEMPERATURES.



GRAPHIC CURVE OF ABSORPTION.

is this true if for any reason the drier should stop running, while at the same time the fire on the grates is permitted to continue burning.

Some Suggestions

In connection with the above-mentioned hazards, the following suggestions may not seem out of place. Care should be taken that pulverized coal is not delivered to storage bins at a high temperature; and to avoid this the gases of combustion from the drier furnace should not be allowed to become hot enough to overheat the coal. In "direct heat" driers, the fire should be so maintained that red-hot cinders will not drop into the screw conveyor feeding the pulverizer. The entire safety of the pulverizing plant largely depends upon the man tending the fire in the drier. If he is careless and builds a big fire on the grate, the chances for overheating the coal in the drier are very great. Or, if he should stop the operation of the drier and at the same time maintain a hot fire, hot coal will result, which might be carried into the pulverizer. Such carelessness would probably result in a disastrous explosion.

Storage bins for pulverized coal should not be placed in any position where they may become heated from furnaces, steam pipes or hot flues.

If a plant has been shut down for several days, delivery of coal from the storage bins through transport lines to the place of consumption should not be permitted before an examination is made to ascertain whether the coal has become heated to such a point that it will ignite when brought in contact with a current or blast of air. This can be done by pushing iron rods into the interior of the stored coal and leaving them there for a short time. When they are withdrawn, the temperature of the rods will indicate whether or not there is any fire or overheating in the bin.

It is believed that the spontaneous combustion of the coal in the storage bin is partly responsible for some of the fires that have occurred in the transport lines which convey the pulverized coal from either the main pulverizing plant or a substation to the furnaces.

A number of cases have been investigated by the bureau in which almost without warning flames burst from the coal lines, when apparently everything had been running smoothly; no stoppage in the lines or in the burners having been observed. However, on several occasions fires had been discovered in the pulverized coal storage bins.

It seems perfectly reasonable to suppose that the coal in the bins had become heated by spontaneous combustion to almost the ignition point and, when this heated coal was conveyed to the transport line, the air from the fan producing the circulating current supplied enough additional oxygen to produce incandescence which in turn, ignited the dust cloud passing through the line. The reason that an explosion did not immediately take place is not definitely known, but is attributed to the excess of coal dust in the line over the amount of air present. In fact, in one instance an explosion, which wrecked the line, did occur at a point just beyond a feed line to the furnace where there was a much leaner mixture of air and dust than at the point where the line was simply burned out.

That an exceedingly dense cloud of coal dust may come in contact with a flame and not ignite had been demonstrated in the laboratories of the bureau. A cloud formed by two ounces of pulverized coal and one cubic foot of air was suddenly brought in contact with a ball of burning oil-soaked waste and a lighted candle, with the result that the flames in the waste and the flame of the candle were both extinguished. In superdusting experiments carried on at the experimental mine of the bureau by George S. Rice, it was observed that a dense cloud of coal dust on coming in contact with a flame at the point of ignition blanketed the flame. However, if the same dust cloud were raised at a point where only a part of the cloud came in contact with the flame, there is a possibility that an explosion would occur. In other words, the pace of an explosion depends upon the quantity of the explosive dust upon which it can feed above the maximum quantity needed for propagation.

From the above-mentioned tests it would seem to be reasonable to assume that whether an explosion takes place or whether the powdered coal in the line burns without violence when red-hot particles are introduced into the pipe lines depends largely upon the density of the dust cloud at that particular time.

Danger From Back-Fire

Some of the fires that have occurred in the powdered coal distribution lines in several plants have undoubtedly originated from "back fires" from the heating furnaces. These, unquestionably, may be caused by the air pressures in the distribution line suddenly dropping below the secondary air pressures. By secondary air is meant the additional air supply, provided by blowers or otherwise, to furnish sufficient oxygen for proper combustion in the furnaces.

The drop in pressure is due to several causes—the fan that furnishes the air current for transporting the coal may be suddenly stopped; the air current may be interrupted by an obstruction in the transport line; or the opening in the burner may become partly closed by small particles of coal coking and adhering to the burner.

The back pressure thus created would tend to draw the heat from the furnace into the feed line, igniting the pulverized coal, and the fire would quickly spread to the distribution line. It may happen, if the primary air is shut off, that there will not be enough oxygen in the line to support combustion until after the air current becomes normal, when the smouldering coal may be fanned into flames.

It is of extreme importance to see that no opportunity is given burning particles to get into the transport line, either from the storage bin or by a "back fire" from the furnace.

Frequent inspection should be made of the burners and any coked particles thereon should be immediately removed.

As often as practicable, at night when the plant closes down if possible, all furnaces should be cut off the supply line, the gate from the pulverized fuel bin closed and the transport line thoroughly cleaned by allowing the fan to force a current of air through it until all the pulverized coal is blown out.

Where furnaces are equipped with individual fuel bins and the coal is delivered into the primary air line by means of screw conveyors, the fuel bins should be placed away from the furnaces. Several fatal accidents have been caused by dust overflowing the line, falling down in front of the furnace door, igniting and flashing up and enveloping the furnace operator in flames. It is true that bins may be fitted with automatic gauges and also completely covered, but even

with these precautions, dust clouds may be formed. Some of the steel companies, in whose plants accidents from overflowing bins have occurred, have placed every pulverized coal bin in the rear of the furnace and just outside the main building. By doing this all danger of a dust cloud coming in contact with hot metal or the flames in the furnace is reduced to a minimum.

In nearly every coal pulverizing plant, there is more or less fine coal dust deposited on the floor, the pulverizing machinery, girders and window sills of the building. If, for any reason, this dust should be raised into a cloud and then come in contact with an open flame, it is probable that an explosion would occur which would wreck the plant.

In fact there was an actual occurrence of this nature in a coal pulverizing plant in which a primary explosion happened in the pulverizer and raised the dust in the building into a cloud, ignited it, and the resulting explosion caused considerable damage to the building, as well as costing loss of life.

Every effort should be made to prevent any accumulation of dust in the building that houses the pulverizer. Certain manufacturing plants in which explosive dust is prevalent have installed vacuum cleaners to keep the buildings free from dangerous quantities of explosive dusts, and such systems have been in use for many years in Northen France and Germany in connection with coal screening plants. This would not be impracticable in a coal pulverizing plant. The recovered dust could be delivered to the pulverized coal bin and used in the furnaces.

It is unwise to depend entirely upon any system of ventilation to overcome the powdered coal dust hazard. It is practically impossible for the air currents produced by the ventilating apparatus to penetrate the angles and corners of the building, where the dust is liable to settle.

In examining storage bins and other places where coal dust may exist an electric light should be used for illuminating purposes instead of an open light. As a further precaution, the electric bulb should be protected by a wire guard to prevent breakage, as there is a possibility that a cloud of coal dust can be ignited by the red-hot carbon filament of an incandescent lamp. Care should be taken to see that the wire is properly insulated, so that an electric arc will not be caused.

To obtain the best results, as regards safety, in the use of pulverized coal as a fuel in industrial plants, it is important that both officials and men be educated to the idea that coal dust is explosive and therefore dangerous; and that under certain conditions it will ignite as readily as gas. This fact is not thoroughly understood and sometimes, only at the cost of life and property is brought home to those connected with the operation.—U. S. Bureau of Mines, Reports of Investigations.

DIFFICULT AND IMPOSSIBLE BELT DRIVES

The following little talk on belt drives is taken from the current issue of "Belts," issued by the Federal Engineering Co., Ltd. It contains some interesting points on belt driving, which will be useful to the power plant engineer:

"Some months ago we invited correspondence from our friends on belt drives with which they were having difficulties. We had a great many letters on this subject and are very much gratified with the interest taken in the matter.

"These letters opened our eyes to a condition existing in many plants that was a great surprise to us. We quite frequently are being asked our opinion as to a belt for a certain purpose, and find the pulley sizes, speeds, etc., make belting conditions practically impossible. We were not, however, prepared for the large number of examples of practically impossible drives that were offered us. The evidence shows such a frequent occurrence of this condition that we thought it would make a very welcome article to offer in this booklet.

"Belting men generally know that the width, weight, flexibility and thickness of the belt are governed by the pulley sizes, the pulley speeds and the horsepower to be delivered. Of course, there are other conditions, such as heat, moisture, etc., that determine the material from which the belt is made, but it is not the purpose of this article to go into the material.

"One of the first problems brought to the writer's attention was a compressor drive in which the belt cracked across the width after being in service for about one year. When a belt cracks across the width it is found in nine cases out of ten that it is due to slipping. On checking up the figures, a twelve-inch double belt was being used for driving a compressor.

"Diam. om motor pulley, 13 in.; r.p.m., 760; diam. of compressor pulley, 4 feet; h.p. of motor, 75.

"On compressor drives, owing to their intermittent nature, we have found that it pays to figure on a belt designed 40 per cent. heavier than for a normal drive. The belt speed of the above drive is approximately 2,600 feet per minute. Now a double 12 in. belt at this belt speed is theoretically good for about 90 h.p., and a belt is needed that will deliver about 106 h.p. This means that the pulleys on the compressor and motor should have faces wide enough to use a 14 in. double belt. This is what solved the difficulty and there is no further trouble.

"Operators of plants often do not know, or frequently forget, that a compressor drive being an intermittent load requires a belt that will deliver considerably more than the rated horse-power of the machine. Our experience has proven to us that a margin of 40 per cent. should be allowed. In this case there was no chance to put on a wider belt, as the pulley width was only 13 in., and this was limited by the position of the machine. A wider pulley could not be put on without changing the layout of the plant. In this case, as the owners considered the latter suggestion impracticable, the only thing that could be done was to put on another 12 inch double belt, keep it well dressed and occasionally apply an adhesive to keep the belt from slipping. This method would possibly give them about 2½ times the life of the belt which they had previously used. This condition, from a belting standpoint, is not good nor economical. It is a makeshift, and many such conditions in one plant would be a serious handicap.

"We do not know why it is, but we find that the manufacturers of compressors generally put the smallest pulley on their product that it will theoretically stand. We have found more trouble from compressor drives for this reason than on any other class of machine.

"In most cases where belts are not standing up we find that by changing the diameters of pulleys or widths of belting makes all the difference in the world between a satisfactory and unsatisfactory drive.

"When our salesmen are endeavoring to introduce our material into a new plant we are generally invited to try our product on the hardest drive. Now, we do not have to experiment. We can tell by a simple process of calculation just what the belt will do. The writer thinks that the many belting houses allow their salesmen to experiment with difficult drives. The house selling the belting generally does so at its own expense, which is proper; but in case of failure the customer loses faith in the product, when the whole trouble may be the result of factory conditions. We were offered a chance to try out one of our belts on a machine where four other firms had failed, one after the other. The drive was impossible. The diameter of the smaller pulley was too small to allow the use of the proper weights of belting, and the faces of the pulleys were too narrow to use a proper width. By changing the pulleys, keeping the proportions as they were before, so that the machine speed remained the same, the problem was solved, and there was no further belt trouble. The man who tried other belting before knew the drive appeared impossible, but the agent wanted to take a chance, hoping that it might stand up. In this case they failed to make a permanent and profitable customer, besides losing the value of the material.

"'We occasionally meet with a vertical drive in which the driver is directly over or under the driving pulley; that is where the belt is perpendicular. It is, of course, not necessary to comment to any extent on this, as all mechanical men know the probable result. The slightest stretch allows the belt to make slight contact with the bottom of the lower pulley, the result being excessive slip and loss of power."

The Relining of a 24 Inch Centrifugal Pump Shell

Use to Which Pump Was Subjected—Extent of Damage—Former Method of Repair—Latest Method of Building Up and Relining—Type of Equipment Used and Saving Effected

By J. H. MOORE

THE following article deals with electric welding and tells of an interesting repair job that is at present being performed by the Thompson Welding Co., Ltd., Toronto, Canada.

The work is that of building up the shell of a 24-inch centrifugal pump, which has been used for sucking up the sand from the Toronto bay. The two halves of this shell are shown in the photograph accompanying the article. Needless to state the sand, grit, and pebbles have worked havoc with the pump shell, which is a steel casting; until at the present time the interior is a mass of holes, grooves, and cavities. Before the pump is fit for use, these have to be filled up, and when we state that some of the grooves are 22 inches long, about 1 inch to 3 inches wide, and ranging from ½ inch to 2½ inches deep, readers can form some idea of the task ahead. Not only are they filling up the holes, but they are building up a ⅜-inch thick lining all around the inside of the shell.

So far, 600 pounds of metal has been used in the building up process, and at least another 150 pounds will be necessary before the work is completed. The small view to the right of the general photograph, depicts the operator busy at work. Some of the cavities can be noticed to the left of the workman, although the photograph cannot attempt to do justice to the number nor size of these grooves.

A Lincoln D.C. 150 ampere machine, mounted on a truck as shown in photograph is being used, and a total time of five weeks is expected to complete the work.

Previous to this particular job, the same company repaired a similar pump last year, although in that case they merely filled the holes up. In spite of this, the pump delivered 980,000 cubic yards after the repair, showing that the owners completed a fine stroke of business in allowing such repair to be effected.

In the present case, the saving will be over $4,000 as a steel casting of the huge size shown would run into quite an expense. On top of that there is the question of delay, so that in many ways the repair proposition is by far the better in this case.

Speaking of the company's activities, Mr. Thompson, the manager, stated that so far this year they had welded 35 boilers on boats at Midland and Port Nichol alone. These included all the C.P.R. passenger boats at these points.

He told of an interesting job performed on the tug Joseph E. Russell. The high pressure cast iron cylinder bottom gland was knocked out, so they proceeded to weld it in place, and made a splendid job of it in quick order. He told of many other jobs performed, but sufficient to state that they have completed various repairs on the great lakes transportation work, from January 1st right up to the 15th of April. They state they had as high as eight machines working at one time.

GENERAL VIEW OF THE OUTFIT AT WORK. A CLOSE UP OF THE OPERATOR.

PETERBOROUGH FILTRATION PLANT

In connection with the new filtration plant of the Peterborough Water Works we are informed that the contract for the two six million gallon centrifugal pumps has been awarded to Escher Wyss & Co., Montreal. This firm's works are located in Zurich, Switzerland. The motors and switchboard will be supplied by the General Electric Co.

HUGE OIL SCHEME

A British oil company is erecting a huge plant for the storage and refining of oil. A new village has been built in the neighborhood of the plant for the accommodation of the work people and staff connected with the enterprise. Between the plant and the port a pipe line has been constructed and the first cargo of oil was recently sent along the pipe. According to a figure received, the scheme will cost roughly $20,000,000.

USING PULVERISED COAL

(Continued from page 29)

going are in the hands of the operating engineers and do not benefit by high-brow application of theories. The engineer who is careful of his every-day equipment and keeps his plant free from accidents of every nature, from flywheel explosion to burned out motors, can operate a pulverized fuel plant successfully without other assistance than his own experience.

In the preceding paragraphs an endeavor has been made to describe briefly the equipment and method necessary to apply pulverized fuel to the steam boiler, and to point out the results to be expected from its use. The merits of powdered coal based on its efficiency and its flexibility to meet varying demands have been set forth and general facts concerning its operation stated.

Engineers in Refrigerating Plants

THERE is at present legislation being put through, if not already passed, requiring men employed in refrigeration plants entirely driven by electric power to obtain certificates similar to their confreres of the steam plant. Just what form this legislation will take we do not know at this time of writing, but we imagine the requirements will be modified to suit the job. It is only right that these men should have to pass a test showing their knowledge of the machinery they are handling, but at the same time it would hardly be fair to expect the same amount of engineering knowledge that would be required of a man who was going to take charge of a plant containing engines and boilers as well as the refrigerating machines, or even without refrigerating machines. The candidate for a first-class stationary engineer's license is expected to know the principles of refrigeration, something of the principles of electricity and the principles of steam, in addition to his practical experience. The position of the man in a refrigeration plant driven by electric power purchased from outside sources is more that of a watchkeeper or attendant than an engineer and the requirements of the position not of so high a standard as that required of the stationary engineer. Service in a plant of this kind should not count the same as service in a steam plant for the purpose of getting full stationary engineer's license, and while a stationary engineer with experience in refrigeration would be quite capable of taking charge of a purely refrigerating plant, a man whose experience was entirely in refrigeration would not be a fit man to assume charge of a combined steam and refrigeration outfit. It seems to us that this legislation will have to be very carefully drawn if it is not going to work a hardship on anyone. Until we have seen the proposed law of course we cannot presume to say what effect it is going to have, but trust that those concerned in having it passed have looked at every angle before going ahead.

Need for Uniform Laws

IN concluding an article on the engineer's licensing laws in Nova Scotia the author speaks of the probability of the passing of uniform boiler construction laws, and of the consequent probability of the passing of uniform engineers' license laws. These are consummations devoutly to be wished, but we have heard of them for so long without seeing any action that we are rather skeptical.

It is hard to understand why the condition where every province has a different law with reference to boiler construction and engineers' qualifications survives. No sane person can maintain that a boiler is safe in one province or unsafe in another or vice versa, or that an engineer who is competent to take charge of a plant of a certain size in Quebec is not competent to run a similar plant when he reaches some other province. Either a boiler is safe or it is not safe, and its geographical position has nothing to do with it, and a man is competent or incompetent whether he is at the North Pole or the South. The thing to do is to have a standard requirement which will enable a man to be certified competent in any part of Canada, and if he does not measure up to that standard to be incompetent in any part of Canada. We fear it will be a long time beore this condition is brought about.

Canada's division into nine provinces, each with its own government, and each to a certain extent independent of the others, militates very much against concerted action on the part of all the different governments. We think that matters like boiler construction and engineer's certificates should be in the hands of the Federal Government, but the Provincial Governments are of course very jealous of their rights, and will not allow the Federal Government to perform any function that they consider theirs by right. So we have in each province a different standard, and we have the condition that tends to make each province and each province's engineers isolated bodies.

We are aware that there are those among engineers themselves who are against it being made any easier for engineers to move from one province to another but we fail to see any good reason for it. What we should consider the most desirable thing of all would be for the various Dominions comprising the British Empire to get together and establish a qualification for marine engineers, so that a man who had obtained a certificate in any part of the Empire would be recognized as a competent engineer in any other part he might wish to go and work in. Air-tight compartments are not good for either men or nations, if they want to develop.

Progress in New Equipment

THE CRAIG DAMPER REGULATOR

A new type of damper regulator is described below, the product of the Craig Damper Regulator Co., of Detroit, Mich., the Canadian agents for whom are the Underfeed Stoker Co. of Canada. The damper control is worked from the draft instead of by the steam pressure, and very close regulation is obtained. It is especially adapted for forced draught work, where it is very desirable to keep the furnace pressure just slightly above atmosphere, so that there is no infiltration of air through furnace doors and other openings.

Operation of the Damper

The drawing below shows the construction of the Craig regulator. It consists essentially of a bell float (A) provided with a water seal within a cylindrical chamber. The under-side of the bell communicates by a draft pipe (B) with the boiler furnace; so that the same draft is carried on the under-side of the bell as is carried in the furnace. The top of the bell is attached to the control valve (C) by a rod. The weight of the control valve and bell is counterbalanced by a small weight (D) which is connected to the valve (C) by means of a cord and a small sheave wheel. Small weights are added to give draft condition desired.

Friction Minimized

The control valve has a comparatively loose fit, and practically the only friction in the movement of control parts is that of the small sheave wheel, which is negligible. This explains the responsiveness, great sensitiveness and accuracy of Craig regulators.

Assuming that it is desired to carry a constant furnace draft of five hundredths of an inch of water a weight (D) corresponding to this draft is placed on the control valve counterbalance. This extra weight tends to raise the belt float, and the corresponding furnace draft of five hundredths of an inch is necessary to create a vacuum under the bell float to maintain equilibrium. In case the furnace draft increases there will be an increased vacuum under the float and it will be pulled down. This will also pull down the control valve, sealing off the valve control ports to the upper side of the piston chamber; the water pressure above the piston will be increased and the piston forced down below the control valve, when one of the ports will be opened and the water pressure released. The control valve has thus forced the piston down and closed the damper sufficiently so that the draft of five hundredths of an inch is again obtained in the furnace and also under the bell, and the float members and counterbalance weight are again balanced. If the furnace draft should decrease the reverse would occur; the vacuum under the bell would not be sufficient to hold it down against the counterbalancing weight and the bell would tend to rise raising the control valve. The water pressure above the piston would be released and it would rise and keep opening the damper until a furnace draft of five hundredths of an inch was again obtained.

Quick Opening

A very important feature of the regulator is the provision for quick opening of the damper. Each port is several times larger than the water inlet opening, so when the draft in the furnace decreases, raising the control valve, the piston rises rapidly, causing the damper to open quickly. This, of course, is highly desirable since it insures proper outlet for the gases when a sudden overload occurs.

Retarded Closing

The reverse is true when closing; the amount of water used being small, the piston will be forced down slowly, giving an easy closing of the damper. This is important in preventing a flattening action of the damper and creating a sudden furnace pressure which in many cases would endanger the fireman.

Since the volume of water supplied to the cylinder is controlled by a throttle valve on the water line, the speed of closing can be readily varied to suit the requirements of the individual installation.

Carrying different furnace drafts merely requires changing the small counterweight. Due to the large cross-sectional area of the bell float, a small change in draft creates a large unbalanced force. This readily overcomes any friction that might occur, and thereby maintains extremely close regulation.

As the amount of water used is very small, the throttle valve in the water line is only opened enough to obtain just sufficient pressure in the cylinder to operate the piston and damper. The pressure used in the cylinder being low, there is practically no wire drawing and wear on parts. This instrument has no springs or delicate parts to get out of adjustment. The bell chamber is connected to the boiler furnace by a pipe line and there is no possibility of damage to the instruments by pressure created in the furnace chamber.

Variations in water pressure do not affect the operation, and the regulation will work on any pressure from 15 pounds up.

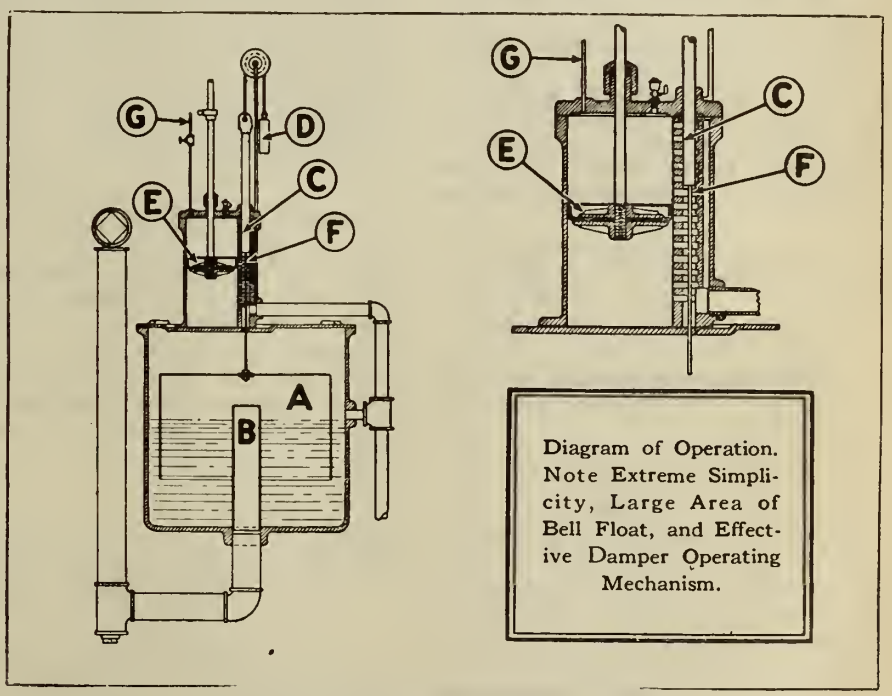

Diagram of Operation. Note Extreme Simplicity, Large Area of Bell Float, and Effective Damper Operating Mechanism.

SECTIONAL DIAGRAM OF CONTROLLER.

CHIMNEY DESIGN

By H. M. BRAYTON
Mechanical Engineer, Philadelphia

DRAFT of a chimney is due entirely to the fact that hot air has a lower density, that is, is lighter than cold air. The air inside of the chimney is heated to a high temperature by the hot gases from the furnace. This column of hot air within the chimney weighs a certain amount in actual pounds which is decidedly less than a similar column of outside air. This difference in weight between these two columns is what makes the draft. The draft as measured in inches of water is actually the difference between these weights less the small amount of loss due to the friction of the moving gases against the side walls of the chimney. This draft will be a maximum at the base of the chimney and gradually become less as we move back toward the ash pit.

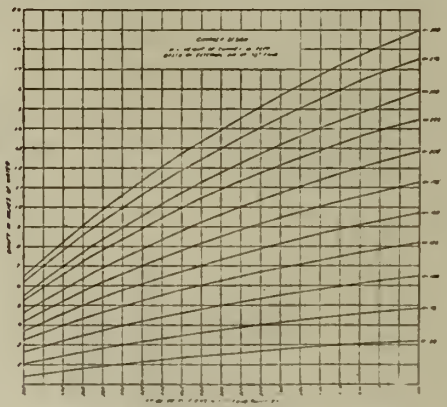
The column of hot gases within the chimney is not of uniform temperature but decreases as we go toward the top. This fact makes calculation on the draft difficult. Until recently it was assumed that the temperature varied from the base to the top uniformly. This theory has proven false by researches conducted back in 1911 on the L Street Station of the Boston Edison Company at Boston. These investigations were carried out by two senior students at the Massachusetts Institute of Technology. From the results of a large number of readings of the temperature at various heights from the ground they were able to plot a temperature height curve. This curve was found to be decidedly not a straight line.

An equation was fitted to this curve of the form in which $n = 25\ H\ Tn = K$.

H = height of any point in chimney above center of flue in feet.
T = Absolute temperature in deg. Fahr. (Temperature Fahr. plus 459.5).
K = A constant the value of which was found to be [75.4032]. (That is log. K = 75.4032.)

The next step was to get the average temperature by dividing the area under the curve by the height. By means of this formula, the specific volume of flue gas, specific volume of air and so forth, it was easy to calculate the draft available from different base temperatures. This calculation is somewhat complicated and will not be given here. The writer has, however, calculated it for the whole required field and incorporated the information in a graph shown in Fig. 1. The ordinate is draft in inches of water, while the abscissa is base temperature. This chart is based upon atmospheric air being at 70 deg. If the air temperature goes above this amount the available draft will be slightly less than that shown by the curves, while if the temperature is lower outside the draft will be more. These are not straight lines but irregular curves. Each point had to be carefully calculated. The various lines showing H from 50 to 300 ft. cover the practical field. Usually we know the base temperature and the draft desired and desire to know the height of chimney required to meet these conditions. Merely find the junction point of these horizontal and vertical lines and the nearest chimney height just above is the one to use. Suppose we have a base temperature of 540 deg. and desire a draft of 1.00 in. of water. The chart shows that we must build a 200 ft. chimney to give these results.

This chart gives a lower draft than most formulae designed for this purpose. Nearly all of the formulae in common use to-day are based on a constant temperature condition throughout the chimney which does not exist. This work was built on experiment and should be more accurate than one devised from theory alone. This formula shows that very little draft is gained by building the chimney above 200 feet. The added



DRAFT AND TEMPERATURE CHART.

cost of the foundation for these excessive heights is seldom justified by the added draft available.

Gebhardt gives a formula for determining the draft from a chimney. This formula, which is based upon the average temperature assumption, is as follows:

$$D = \frac{H}{7.64} - \frac{T_2}{7.95}$$

Where D = Draft in inches of water.
H = Height of chimney in ft.
T_1 = Temperature of outside air deg. absolute.
T_2 = Temperature of chimney gases in deg. absolute.

This formula gives much higher drafts than the previous formula. For a temperature of 540 deg. for the chimney gases and a 200 ft. chimney, as assumed in the other problem, we would here have not 1.00 in. of draft but 1.40 in.—a 40 per cent. increase. Actually, we would not get this. Is it not always better to err on the safe side? If we plan our chimney on this formula we are apt to find after it is all built that sufficient draft is not available to run the furnaces properly. This formula is out of date and in reality is seldom used by specialists in this branch of engineering. Years of practice have enabled them to design properly a chimney to meet practical needs.

Capacity of Chimneys

Chimneys must not only be able to give the required draft, but they must also be sufficiently large to carry away the volume of gases generated by the coal burned. This rate of combustion is always known and the interior area of the chimney made accordingly. The cross section area may be based upon the boiler horsepower connected to it or it may be based upon the grate area. Either method reaches the same result. Kent's formula, which is well known, follows:

$$\text{B. hp.} = 3.33\ E \sqrt{H}$$

Where B. hp. = Boiler hp. connected to the chimney.
E = Cross section area of interior of chimney in square feet.
H = Height of chimney in feet.

By transposing this equation we get the one more often used as follows:

$$E = 0.30 \frac{\text{B. hp.}}{\sqrt{H}}$$

Some engineers prefer to proportion their chimney area on the grate area. In practice it has been found that satisfactory results will be had if the interior area of the chimney is made one-tenth (0.10) the total grate area which it serves. If the plant is small, say not over two boilers, this ratio should be increased to one-eighth. This ratio depends to some extent on the height of stack. When the chimney is low, say not over 100 ft., the area should be made at least one-seventh the grate area.

Another formula for determining height of chimney, which is very simple to use, should also be mentioned here.

Where H = Height of chimney in feet.
d = Draft in inches of water.
K = A constant which varies with the base temperatures = 0.007.

This equation gives more nearly the true results. It shows that a draft of 1.00 in. of water requires about a 180-ft. chimney.—Southern Engineer.

HELPING THE OLD-TIMES

The spirit in which British industrial concerns interpret their duty to their employees is exemplified by the action taken by two of the leading railway companies in connection with superannuation allowances for old servants. Owing to the change in the value of currency since the war the original allowance had become inadequate and the companies voluntarily decided to increase the allowances to superannuated servants and also to improve the scale of benefits for those servants entitled to superannuation. This action is all the more striking as the only fund at present available for such concessions is the dividend fund. The additional amounts, therefore, come out of the shareholders' pockets.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

CONDENSING AND NON-CONDENSING

Question:—When changing over from condensing to non-condensing is it necessary to alter the setting of the valves in a four-valve engine?

Answer:—Generally when changing from non-condensing running to condensing, as often occurs at the end of the winter season, when heating is no longer required, it is found necessary to make some alteration in the setting of the exhaust valves. This is accounted for by the difference in the terminal or exhaust pressure, and consequently the volume of steam remaining in the cylinder when compression takes place. When running non-condensing the pressure in the cylinder when compression begins is usually something above atmosphere, and the pressure rises by the end of the stroke to something near the initial pressure. When condensing the pressure in the cylinder will be only about 5 pounds absolute and, therefore, the compresssion pressure before the opening of steam will be considerably lower. In order to insure smooth working, therefore, it is necessary to make compression take place a little earlier, so that there is more steam to compress, and thus the pressure will be brought nearer to that obtained when working non-condensing.

BOILER HEATING SURFACE

Question:—Please tell me how to find heating surface of a H.R.T., 16 x 66, with 66 tubes 3½ inches diameter. What is the rule for finding diameter and weight of a flywheel for an engine 10 inches x 16 inches and the speed the engine is to run?

Answer:—The heating surface of the boiler may be found by taking the area of half the shell, and the area of the tubes on their outer surface. This will be found as follows. The shell being 66 inches diameter or 5.5 feet, the area will be:

$$\frac{5.5 \times 3.1416 \times 16}{2} = 138.23 \text{ sq. feet.}$$

The area of the tubes will be:

$$\frac{3.5 \times 3.1416 \times 16 \times 66}{12} = 967 \text{ sq. feet.}$$

and total heating surface is:

138.23 + 968 = 1,106.23 sq. feet

and with 15 square feet to a horsepower the rating would be 1106.23 ÷ 15 =73.75, roughly 74 h.p.

With regard to the weight of flywheel, this will depend on so many different factors that one cannot give an answer off-hand. The point of cutoff has a great deal to do with it, the horse-power to be developed, which again depends on steam pressure and engine speed. For an engine of the size you mention the piston speed will be from 500 to 600 feet per minute. That would be 250 revolutions, assuming it is a high speed engine. One of the most easily applied formula is that of J. B. Stanwood, which is as follows:

$$W = 700{,}000\ d^2 s \div D^2 R^2$$

in which W=weight in pounds, d=dia. of cylinder in inches, s=stroke in inches, D=Diameter of wheel in feet, R=Revolution per minute. The co-efficient may be varied as follows for slide valve engines, 350,000. For same electric lighting duty, 700,000. Automatic high speed engines, 1,000,000. Corliss engines ordinary duty 700,000, and electric lighting 1,000,000.

The average fly wheel radius is from 3 to 5 times the length of the crank, according to Rankine. This gives the figure for D approximately.

$$W = \frac{700{,}000\ d^2 s}{D^3 R^2}$$

$$= \frac{700{,}000 \times 10 \times 10 \times 16}{4 \times 4 \times 250 \times 250}$$

=1120 lbs.

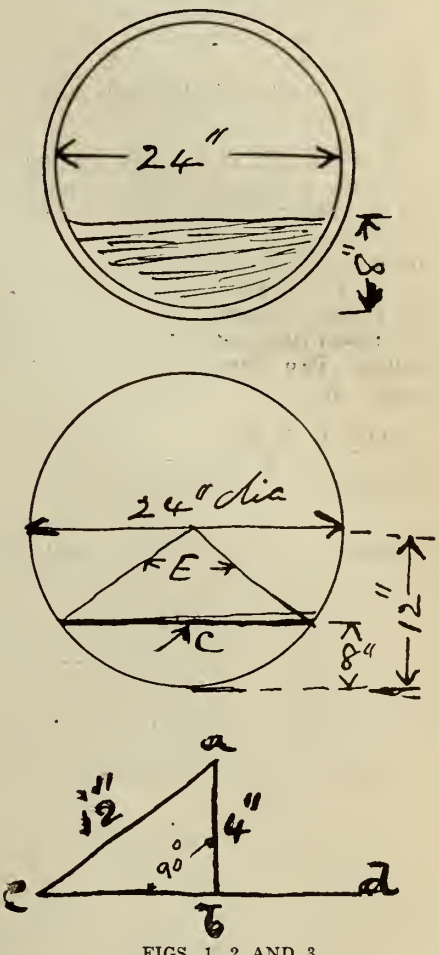
This formula is based on the assumption that the lowest piston speed will be 480 feet per minute.

* * *

CAPACITY OF TANK

Question.—How many gal. of oil does a circular tank 24 in. x 96 in. contain when the depth of the oil in the tank is 8 in., the tank being in horizontal position.

Answer.—First find the area of the cross-section of the oil. As there are many rules by which we can get the area of a segment of a circle approximately, a very convenient formula, often used by engineers, that does away with the necessity of applying the principles of trigonometry and which gives almost exactly the required area is given here as follows:



FIGS. 1, 2 AND 3.

$$a = \frac{4h^2}{3} \sqrt{\left(\frac{D}{h} - .608\right)}$$

In which a = area of segment.
h = height of segment.
D = Dia. of the circle of which the segment is a part.

Substituting

$$a = \frac{4 \times 8^2}{3} \sqrt{\left(\frac{24}{8} - .608\right)}$$

$$a = \frac{4 \times 64}{3} \sqrt{(3 - .608} = (85.33 \times 1.546) = 131.9 \text{ sq. in.}$$

Then (131.9 × 96) = 12662.4 cu. inches of oil in the tank. A British gal. contains 277.274 c. in. The tank, therefore, contains

$$\frac{12662.4}{277.274} = 45.66 \text{ gal. nearly.}$$

The formula stated above is very convenient and almost exactly correct. It does away with the necessity of applying the principles of trigonometry, which, to some engineers, are a somewhat tedious affair. However, we will work it out by another formula, as it may be interesting:

$$a = \frac{\pi 8^2 E}{360} - \frac{c}{2}(r - h)$$

Here we must find the angle (E), also the cord (c).

First we find the angle. To find ½ the angle we have the radius 12 in. and the side, which you can see is = (12 — 8) = 4in. That is when we drop a perpendicular from the center of the circle on the cord (c) we have a right triangle, the sides of which are ½ the cord, and the dotted line, and the hypo will be the radius. Two sides are known and one angle. In

$$\text{Angle } E = (2a)$$

$$\text{Cosin } a = \frac{4}{12} = .3333$$

Whence a = 70 deg. 30 m. and E = (70°—30') × 2 = 140½ deg.

Cb = cosin a = 12 × sin. 70° — 30'.

Cb = 12 × .94264 = 11.31168 inches, or say 11.31.

The cord c bd = (11.31 × 2) = 22.62.

Now we can apply the formula

$$a = \frac{\pi r^2 E}{360} - \frac{c}{2}(r - h)$$

Substituting

$$a = \frac{3.1416 \times 12^2 \times 140\frac{1}{2}}{360 \times (12 - 4)} - \frac{22.62}{2}$$

$$a = \frac{63560.7}{360} - \frac{22.62}{2}(12 - 4) =$$

$$a = \frac{63560.7}{360} - 11.31 \times 4 = 131.26$$

sq. in.

Another way that is very simple is to lay off to scale and run the planemeter over it as you would get the area of an indicator card.

Now, some of our readers are good at transposition of formulas, and some of them may like to try this. Transposing the formula

$$a = \frac{4h^2}{3}\sqrt{\frac{D}{h}} - .608$$

Find the height of the oil in the above tank when it is 3-5 full.

COMMUTATOR SPARKING TROUBLE

In conversation with the engineer aboard a certain tug in Halifax the other day, the chief mentioned some trouble he had with a sparking commutator on a small lighting turbo driven D. C. generator. He explained that he had electricians looking over the job a dozen times who assured him that the generator was in good condition, the brushes properly spaced and properly set, yet they could not stop the sparking on the commutator.

I asked the chief if I could look at his generator. "Sure," he said, and he went below with me and obligingly started her up. Well, she was sparking all right, although I have seen them much worse, but she was also vibrating badly and as the commutating speed was high I knew that the commutating trouble was partly, if not entirely, due to vibration. The machine seemed to be badly out of balance. Where the ball thrust should be there was nothing but the casing. I put my lead pencil up to the end of the shaft and found the end play to be about one-quarter of an inch. That is a lot for even a small turbine, and I steadied the rotor by holding the pencil against it and to my surprise the chief told me that the sparking stopped (I was at the other end of the machine). I questioned him about the speed, but he could not tell it exactly. I wondered why but I found out when he shut down that there was no governor on the turbine. The steam was controlled by the throttle. When the lights were bright the speed was assumed to be as it should be. This is not necessarily so, since the amount of resistance cut in will determine the voltage regardless of the speed. The generator had been rewound and statically balanced. A new wheel had been put on the turbine shaft and statically balanced, but the set was never balanced for running (dynamic balance). I looked for a crevice in which to stick a bit of lead to try for balance but could not find any on the outside of the revolving element, but I explained to the engineer how we used to insert balancing plugs in turbo generators. He brought me the old wheel that had been removed and I was able to show him the holes tapped in the disc for balancing and I may say that I had a great deal of respect for him taking it as he did. He was not too big feeling to take pointers on something that he just didn't happen to be clear on before, and the same fellow gave me a few tips before I left him.

Now he is going to balance his machine and take up end play and take some of the slack out of the bearings and if he can find the maker's address he is going to get a new governor and ball thrust, and if he finds that that doesn't cure all his troubles, well, I may as well keep my nose clear of Campbell's Wharf, as Conrad is a pretty burly looking fellow. J. A. McG.

WHY BELTS ARE STIFF

By RALPH BENTZ

An excellent way in which to make a study of belt fibre action is to take a pad of scratch paper, a magazine, or something of that sort, and bend it. It is easy to bend a pad of paper when the motion of the ends of the paper is unrestricted. You will note that one sheet slips along on the other a short distance. There is no tension on the convex side, or compression on the concave side of the bent pad. Glue the ends together, or hold the ends tightly with the hands, however, and it will be found more difficult to bend the pad. There will be a "buckling" on the concave side. The convex side will be in tension.

Next glue the complete pad together by saturating it in glue and drying, and you will have a chunk of material that will be as difficult to bend as cardboard, or even as difficult as wood. This is because buckling becomes impossible on the concave side if the gluing job is properly done, and there is no sliding. There is a certain plane close to, or at the centre, that is neither stretched nor compressed when the "board" is bent. That plane is called the "neutral axis." On the concave side of that axis the fibres of the board are in compression. On the convex side the fibres in tension.

The thicker the board the greater the force required to bend it. This is true because the fibres farthest away from the neutral axis have a longer lever arm than in a thinner board. And that is why steel I-beams, channels, Z-bars, etc., are made for engineering structures—to put the outside steel fibres as far away as practicable from the neutral axis.

This explains why belts may be stiff or pliable. The dry, hard leather belt that is not lubricated in its fibres is naturally stiff because the fibres have difficulty in rubbing one over the other. Thus you will find it more difficult to bend a pad of sand paper or emery paper, for example, than a pad of smooth writing paper. The dry, hard belt does not permit its fibres to slide on one another so easily on the tensile side nor on the compression side. The treated lubricated belt on the other hand, permits its fibres to slide with greater freedom. There is no "grinding" as in a pad of sand paper.

This method of studying the belt will clear away many of the points that have possibly been troubling many belt users. It explains why double or three-ply belts are stiffer than single belts. It explains why treated belts are more pliable than untreated belts of the same thickness. It shows why lapped cement joints have a tendency to loosen or "shear" and why the cement used in any belt must be good. Pick up a pad or magazine one-fourth of an inch thick and try it.

Low Pressure Heating Systems

HEATING systems supplied by low pressure steam from central heating stations are, as a rule, well protected from excess pressure by relief valves of ample capacity, and the whole system is usually under the management of competent and careful engineers who know their business. Moreover, these systems are daily inspected by the plant operatives and periodically by duly qualified Government inspectors or other recognized officials, and there is little danger of accident from over pressure. But in spite of the best regulations and frequent inspection accidents do happen, often with disastrous results and sometimes accompanied by loss of lives. To the duly qualified engineer there is no need to point out the precautions that should be taken with a view to safety, but there are engineers and attendants in charge of steam heating plants that may benefit from a few remarks. This applies particularly to those who operate small plants carrying high pressure steam for manufacturing purposes and reduce the pressure by means of a reducing valve for the heating system, or in some cases by throttling down on a valve at the boiler and controlling the supply of steam manually. In the latter case when more heat is required the valve is opened a little and when the steam supply is sufficient closed correspondingly. This practice has many disadvantages apart from the point of safety.

The Reducing Valve

The reducing valve is a device that, properly installed and operated, will maintain an almost constant pressure on the low pressure system even when the boiler pressure varies considerably. The fundamental principle of the operation is —that the low pressure steam acting on a large area will balance the high pressure steam acting on a small area. Let us take for example a case where the boiler pressure is 100 pounds per square inch and the steam pressure on the low pressure side is to be maintained at 10 pounds per square inch and ignore the weight of the valve disc, which is free to move, that is to close or open. Now if there be a continuous stem through to a cylinder above and below, each end of the stem to carry a piston, one cylinder to be connected to the high pressure steam supply, the other to the low pressure side, the area of the piston that is acted on by the low pressure side would have to be ten times greater than the area of the piston that was in contact with the high pressure. If we ignore the weights of all the parts that are free to move, we can prove this by simple arithmetic. Thus: Let us say the area of the high pressure piston is 10 square inches and the area of the low pressure is to be found. Let the pressures be as stated, i.e., 100 pounds and 10 pounds. Let (A) be the large piston area and (a) the small piston area. Then

$$10 \times A = 100 \times a \text{ or } 10A = 100 \times 10$$

$$A = \left(\frac{100 \times 10}{10}\right) = 100$$

The area of the large piston must be 100 square inches so that when there is 10 pounds per square inch on the low pressure side it will balance 100 pounds on the high pressure side and the valve remains in a neutral position. Now if the pressure on the low side tends to go above that point it will overpower the high pressure and the valve will automatically close and prevent more steam going over to the low side. We can also prove this by simple arithmetic.

Let us say that the pressure on the low side has increased ½ a pound per square inch and let the high pressure be (P_1) and the low pressure be (P_0) and the areas as before (A) and (a).

Then $(A \times P_0) = (a \times P_1)$ or $(100 \times 10\frac{1}{2}) = (10 \times P_1)$.

$$P_1 = \frac{100 \times 10\frac{1}{2}}{10} = 105 \text{ pounds per square inch.}$$

That is, an increase of ½ pound on the low side is equal to 5 pounds on the high side and so long as the pressure on the high side does not increase the valve must close. This also proves that under these conditions a variation of 5 pounds on the high side means a variation of 1-10 or ½ pound on the low side. Now if the boiler pressure falls off 10 pounds per square inch the heating system pressure falls off 1 pound. Later on we will take up the description of the various kinds of reducing valves in use, and how to take care of them and adjust them in practice. Now where does the safety valve or relief valve come in.

The Relief Valve

Let us say that something goes wrong with the reducing valve, and it fails to close when the pressure on the low side goes up. The disc of the reducing valve may not be exactly steam tight, or may be cracked. If some one closed the valves on the heaters the steam leakage through the damaged reducing valve would allow the pressure to build up. It is easy to see that the whole heating system would be charged up with steam at the boiler pressure, provided that there was no safety valve between the reducing valve and the heating system. The result might be a disaster. It may be said that the danger is not so great when the heating system consists of ordinary wrought iron or steel pipe with standard fittings but where there are cast iron heaters or tanks and receivers of large diameter there is great danger. Therefore there should be placed in every heating system that is supplied from a high pressure boiler, whether the steam supply is regulated by hand or by a reducing valve, a safety valve that has ample relieving capacity to relieve all the steam that could pass through the reducing valve when wide open without a dangerous increase of pressure.

The safety valve should be placed close to the reducing valve and on the low pressure side in every case. The size of safety valve of course depends on the quantity of steam that must be relieved per hour and the absolute pressure. The following formula is for the area of a safety valve:

Let (a) be the area of the safety valve in square inches.

Let (w) be the weight of steam to be relieved per hour.

Let P be the gauge pressure pounds per square inch.

$$\text{Then } a = \frac{0.22 \times w}{(P + 15)} \text{ and } w = \frac{(P + 15)}{0.22}$$

also $P = (0.22w) - 15$.

The installation of a safety valve of large relieving capacity at low pressure is very important, since what often happens when the reducing valve goes out of order is that the by-pass is opened wide out and the throttling is done from some convenient point maybe near the boiler and there is danger of it being thrown wide open by someone. Sometimes the reducing valve is blocked open and no attempt made to repair it when it goes out of order or the disc maybe taken out. This often happens where the reducing valve is installed without a by-pass.

The best reducing valves ever made will go out of order sometimes and besides there is always a chance of someone tampering with the adjustment. The result is the pressure on the heating system may become excessive, if not protected by a relief valve.

Wants Generator—G. L. Whidden, Lower Wentworth, Nova Scotia, is looking for a good, used, direct current generator, 30 to 40, on 110 volt, capable of giving from 600 to 750 amp. He would like to secure this complete with switchboard. He is also interested in a used lighting plant, with or without batteries.

Wants Feed Pump.—Vineland Canneries, Ltd., of Vineland Station, Ont., want to secure the following equipment. They would consider used, if in first-class shape:—Duplex boiler feed pump for two 125 h.p. boilers, 2 in. intake and 1½ in. discharge. Along with this is required a number of tees, nipples, check valves, etc. W. A. Whitney is the manager of the concern.

How They License Engineers in Nova Scotia

The Method Under the Colliery Engineers' License Law—In Other Steam Plants No License Required—The Licensed Engineers' View—A Particular Case—A Uniform Law

Special to "Power House"

SINCE 1894 there has been in effect in Province of Nova Scotia an act, known as the "Mines Regulation Act," its purpose being to regulate and cause to be examined by a board, the officials entrusted with the operation of coal mines, both underground and overground. Thus engineers are required to pass examinations in order to obtain certificates, entitling them to operate steam plants in connection with coal mines.

This act has been amended now and then for the past 15 years, with the result that the Colliery Engineers' License Law is reasonably comprehensive, and it may be said that so far as the coal mine operative engineers and hoistmen are concerned they must to-day hold a certificate of competency before they can operate a steam plant of more than 100 h.p. capacity at a pit-head. Why the minimum is placed at 100 h.p. and no mention of the steam pressure carried is not quite clear. But as the law stands at present a young man, 18 years of age, who has served six months as a fireman and can furnish proof of good conduct, and is a British subject, can sit for a certificate of competency and, if successful, may operate a steam plant of 100 h.p. and up to 200 h.p. carrying any steam pressure. More than that, he may operate his plant without inspection of his boiler, if the boiler is not insured, as the law does not provide for boiler inspection. Remember this 18-year-old engineer is (if he holds a certificate from the board) in full charge of the plant. I am not saying that 18-year-old boys are operating 100 h.p. plants in the capacity of engineer in charge. I am merely stating the law.

Other Steam Plants

Now we will leave the colliery engineer at that for the present and see what effort there is made to regulate other steam plants. I think I can show that there is none whatever, so far as license law or inspection regulations are concerned. It is quite common to see steam plants in the coal mines districts operated by engineers who have no license. They can do this lawfully so long as the plant is not part of the mine equipment. In some cases the boilers of the plant are inspected by the boiler insurance inspector. This applies only to boilers that are insured, and I am not just now concerned with insurance. Now then, coming down to steam plants that are outside of coal mine districts, Stationary plants in cities are operated by non-licensed engineers and are under no regulation whatever. Traction engines with boilers, road machines, donkey plants for contractors on construction work, steam heating plants in large public buildings and apartment houses, steam laundry plants, factory plants of all descriptions ranging all the way from 10 h.p. to 5,000 h.p. and pressures from 5 pounds to 200 pounds per square inch, are entirely at the discretion of the owner or manager as to who shall operate these plants and how they shall be operated in so far as the law takes any notice. I do not say that those engineers in charge are not qualified, in fact I know some of them are excellent engineers, but they haven't a scrap of paper to show that they are. On the other hand, I know that some of them are not qualified and who are not qualified to sit for an engineer's examination, and who would not be allowed to operate a steam plant of any kind where there are regulations in force. Some of the plants in charge of incompetent men may have a certain measure of protection in the fact that they are periodically inspected by the insurance inspector, but the insurance companies want business and can afford to take some risk. Sometimes they may take more risk than they know of.

Who is going to say that an engineer is or is not competent in the absence of an examination board? One may say that it is just one man's word against another's. I have had men come to me as engineers who were quite ready to step in and take full charge of a watch, who had a pocket full of recommendations, etc., who did not know the A.B.C. of steam boiler operation. On the other hand, I have had men come to me who did not have a scrap of paper who turned out to be A1 men.

The Licensed Engineer's View

Now let us have a look at the situation from the licensed engineer's standpoint. In order to take charge of a coal mine plant he has had to go up for examination before the board, year after year, until he now probably holds a 1st Class Engineer's Certificate. That certificate is good in any colliery steam plant in Nova Scotia and nowhere else. So long as he sticks to coal mine plants, he is regarded as a competent engineer. If he goes to a city plant he might just as well leave his paper at home, it will make him no friends in the city plant. In fact he would stand in better if it was not known that he had one. The master mechanic of the plant requires no ticket, the chief operating engineer probably had no ticket, and the manager or superintendent probably never heard of such a thing as a ticket for a stationary engineer. He will likely want to know why you require a ticket to put coal in the boiler furnace or put oil on the engine. If he goes to Montreal or Toronto or Winnipeg or any other place in the West with his ticket, it won't qualify him to fire a sawmill donkey boiler, let alone a steam plant of any size. Why? Because a certificate that is no good except in one corner of Nova Scotia is no good anywhere, and who's fault is it? We are going to look into that right now.

We can hardly blame the owner or manager of an isolated steam plant for being indifferent to any form of license law or boiler inspection regulation. He is like the fool that we all meet at some time or other, who did not know the gun was loaded. If he kills himself, we feel a little sorry for him. If he kills someone else—well, it was an accident; anyhow, we won't hang him and he is left free to do it again if he happens to forget. So the aforesaid owner, like the man with the gun, does not know that his steam boiler or his engine flywheel are loaded and are more deadly than a gun. There is no use telling him, he simply can't see it. Of course, he can't see it.

A Particular Case

The following case took place not 1,000 miles from one of the coal mine districts. The inspector of factories, under the Factory Inspection Act, had occasion to look in on an engineer when making the rounds of a certain plant, and noticed that every once in a while the engineer would adjust a very substantial looking hook. After a little he would disengage it, and not seeing any sense in the thing at first, the inspector became curious and investigated. This is what he found. Mr Engineer had a system of compound levers and chains so arranged that he could hold the safety valve down and leave it locked down close, without having to go up on top of the boiler to do it. When cautioned by the inspector about the danger (the factory inspector has nothing to do with boiler inspection) the engineer (?) showed him that he know something, "He was no hick, he wasn't." He explained, "This boiler was tested to so and so pounds per square inch and she didn't explode. Besides you should know, if you know your business, that this boiler was constructed with a factor of safety of 5, and there is no danger of an explosion even if I increase the pressure to five times the blowing-off pressure."

That man should have been fired on the spot, but it couldn't be done—he was in charge of the plant, and as long as the owner could get power he was

(Continued on page 42)

The Purification of Boiler Feed Water

Process of Continual Blow Down Used in Conjunction With Hot Purification—The Author Describes His Own Process—Various Causes of Corrosion and Need for De-Gassing Water

By PAUL KESTNER

A JOINT meeting of the Institute of Mechanical Engineers and the Society of Chemical Industry was held in London on March 4, to hear a paper by M. Karl Kestner on "De-gassing and Purification of Boiler Feed Water." Captain H. Raill Sankey, president of the Institution of Mechanical Engineers, was in the chair, and Sir William Pope, F.R.S., President of the Society of Chemical Industry, was also present. As will be seen, the meeting was regarded as of considerable importance, inasmuch as it brought together for the first time mechanical engineers and chemists. M. Paul Kestner is founder and president of the French Society of Chemical Industry.

M. Kestner said that the necessity for enabling boilers to steam for long periods without scale or corrosion becomes more urgent every day. The old lime and soda process had been improved and reduced in size, and heat had been used to accelerate the operation, but not always with success, for in some instances a concentrated soda solution was formed in the boiler.

The paper dealt in detail with the process of continuous blowing down used in conjunction with hot purification. Hot purification effects a thermal saving, and has the further advantage of eliminating the gases dissolved in the feed water by the reduction in high solubility at high temperatiure. The speed at which the reaction takes place in the purification of water by soda alone, or lime and soda, can be accelerated by heat, and the settlement of the precipitate can be hastened by agitation, the effect of which is to cause accretion and increase of size of the particles. If the agitation is caused by a stream of water carrying air with it, the water becomes saturated with oxygen and corrosion results.

In water-softening processes generally, rise of temperature ensures (a) increased speed of reaction; (b) reduced viscosity of the water; (c) reduction of the carbonates of the alkaline earths to carbonates; and (d) reduced solubility of calcium sulphate and partial precipitation without the use of reagents.

Whatever method of purification is employed, all the salts carried into the boiler by the feed water become concentrated in it. In general some calcium carbonate remains in solution in the water and when the concentration produced by evaporation becomes sufficiently high it is deposited on the walls of the boiler or in the tubes, forming incrustation, which is harder the more slowly the deposit is made. In boilers generating steam very rapidly, the deposits are also formed rapidly, and may accumulate in the tubes notwithstanding the violence of the circulation. The usual remedy is periodic blowing off from the lowest point in the boiler, and, to be effective, a large actual quantity of water must be blown off at each operation, even though such should not form a large proportion of the boiler contents. The continuous blow down allows the calories to be saved by passing the blow-down water through a feed-water heater, the mud being deposited in a trap during the process, together with the salts that had been retained in solution owing to the high temperature of the liquid. The only loss occurs in the actual removal of the mud and salts, which form a relatively small quantity The blow-down water freed from the impurities is then returned to the boiler. This prevents the concentration of the soluble salts to an extent at which they would constitute a danger.

The process of continuous blowing down permits the contents of the boiler to be renewed frequently; it eliminates mud before it has time to accumulate, and at the same time allows the use of soda for the reduction of the calcareous bicarbonates. The feed water, therefore, contains sodium carbonate and bicarbonate; the latter is decomposed in the boiler to carbonate, and the carbonate in its turn is dissociated in the presence of water with a reversible condition of equilibrium in functions of the initial concentration and the temperature, thus CO_3Na_2 H_2O $2NaOH$ CO_2, hydrolysis giving more caustic soda the higher the temperature. With continuous blowing down, the water containing caustic soda and carbonate of soda is used to purify the make-up feed, the caustic soda reacting more rapidy on the calcium bicarbonate than would calcium oxide. It is, therefore, said the author, of great importance to combine purification by soda with the continuous blowing-down process.

M. Kestner then described the Kestner continuous blow-down process, the apapparatus consisting of a steam separator, a central reservoir receiving the blow-down liquid, an annular chamber surrounding this reservoir, from which it receives heat and into which the purified blow-down water is decanted. The steam passes into a re-heater in which it heats the feed. The decanted feed mixes with the blow-down as it leaves the central chamber, and then passes to the annular chamber in which precipitation and settlement take place. Soda is added through a water meter in proportion to the make-up feed. Valves are provided for separating the mud.

Discussing the conditions in which distilled water is used in industry, the author stated that this water is very different from that used in the laboratory. Owing to the rate of evaporation, particles of water containing salts are carried over, so that the distilled water contains numerous soluble salts in small, but by no means negligible quantity, and in the boilers using distilled water it becomes in time a fairly concentrated liquor. Boilers working with distilled water, therefore, require to be blown down occasionally, but it is not necessary to remove a large amount of liquid, the amount being usually only 1 or 2 per cent., the saline solution being replaced by distilled water. Even when an evaporator is used, the continuous blowing-down method can be adopted, and, in conjunction with de-gassing, enables a complete closed water circuit to be arranged in a central station using distilled water. Where distilled water is used, continued the author, there can be no doubt as to the cause of corrosion. Oxidation of the plates can only be produced by oxygen dissolved in the feed water and set free in the boiler, and the effect is greater with intermittent working. The theories of corrosion were discussed, and the need for de-gassing purified water was pointed out, it being explained that the critical concentration, at which maximum corrosion by salts is effected, must be exceeded after a few hours' work in ordinary boilers. Electrical and electrolytic action were next considered as well as the hydrolysis of magnesium chloride, as was the action on steel of carbonic acid gas alone and in the presence of oxygen, as well as the formation of oxy-salts under certain conditions. As regards the elimination of oxygen in solution, the author showed that the air dissolved in water contains roughly 33 per cent. of oxygen, and a titrating method of controlling the de-gassing, devised by M. Gaston Paris, of the Kestner laboratory, was illustrated.

The elimination of the oxygen dissolved in water may be effected either by physical or chemical methods, or by both. Of the former, the principal methods are agitation of the water, the action of temperature, and the action of vacuum. These may be used separately or in the majority of cases in combination. Of chemical methods, the only one that is important is the action of highly oxidisable iron, which absorbs the oxygen from the feed water. Brief descriptions were given of the methods and appliances for de-gassing by physical

means, and M. Kestner then discussed the more important classes acting by (a) combined physical and thermal means. The Cochrane, Webster, Weir and Chevalet heaters are placed in this class. The Aerex was said to have certain advantages over these, which are adopted also by Seigmon-Schmitt. (b) Vacuum de-gassing. In this class were placed the vacuum appliances of Meihof (Halvor Breda) and Griesheim Elektron Lauta (Balke and Company) and Deutsche Sanitas Werke. The de-gassing apparatus of the Elliot Company, of America, working at about 100 degrees Cent., was also mentioned. (c) Chemical de-gassing. Under this heading it was explained that the chemical methods in use are all based on one principle of using very easily oxidisable iron, which, under suitable conditions, enables de-gassing to be obtained down to only traces of oxygen. As the result of much experiment, the author has found that for this purpose manganese is a catalytic agent of great importance, and a suitable manganese cast iron has been found. Mention was also made of two German de-gassers, the Seiffert and the Halsmeyer, which work with rusted iron, and there is also an American apparatus, due to Professor W. H. Walker, styled a "deactivator."

The author's experiments have led to the design of an apparatus due to the discovery that when an iron de-gasser which had become completely rusted was left at rest, it was found after a day to have undergone a change, and from red rust to have become greenish-black, due to the reaction of ferric hydrate under the influence of the iron. This led to the invention of the Paris de-gasser, which works on the regeneration principle; in one form by means of two vessels containing iron turnings through which flow takes place alternately, and in the other form in a single vessel with filters at each end and a valve arrangement for permitting the direction of flow to be altered. The amount of iron used in the apparatus is stated to vary from 1 to 3 grammes per ton of water treated, and the amount so used corresponds to the weight of boiler plate saved from destruction. Finally, the suggestion of a water circuit closed from atmospheric contact was discussed and the combination of a de-gasser with such a system was recommended as a means for preventing any harm due to access of oxygen from accidental causes.

A fire which broke out late Saturday afternoon, May 8, at Queenston, in the power house of the Queenston-Chippawa development, damaged plant and equipment to the extent of about $50,000. While the actual damage itself seems large, it will not retard the schedule for the completion of the work at all, nor will it cost the Hydro-Electric any money. The origin of the fire has not been determined.

How They License Engineers

(Continued from page 40)

satisfied. As he was getting sufficient steam pressure under the present engineer he no doubt thought he had a first class man. What would happen to you with your first class ticket in that plant if you took the job and tried to convince the owner that the boiler was not safe at treble or double the working pressure? Why, you'd get fired on the spot. The other engineer could get steam, but you had cold feet. That's the way he might look at it.

Now, again, whose fault is it that such conditions are allowed to exist I may say that I believe that is partly the fault of the engineers who do not know that the gun is loaded. They allow the ignorant man to keep on operating and the owner likes it. No, if an engineer is not a safe man in a colliery steam plant how can he be a safe man in any steam plant

Probably the real reason that there is no regulation at present outside of the mining districts is this. In the early days of Nova Scotian industrial development, the coal mines were the only places where steam was used to any great extent. The first stationary steam plants of any importance in the province were hoisting and pumping plants at the collieries, and for years before this the British collieries regulations were in force, under which the colliery engineer had to pass an examination before a board. The Nova Scotia Government, following in the footsteps of the Mother Country adopted and put into force the Mines Regulation Act, and it is only within recent years that industrial development has spread to other centres than collieries. With this development has come the Factory Inspection Act of Nova Scotia and the Inter-Provincial Steam Boiler Act, which is soon to be adopted in Nova Scotia and of which something will be said at a later date.

It would appear that the Province of New Brunswick is leading Nova Scotia in the matter of steam boiler inspection and engineers' license regulations, as there is now in force in that province a law that requires the engineer of a steam plant to have a license to operate steam plants, whether in the cities or outside. The New Brunswick Boiler Law will be discussed through the columns of Power House at a later date. At present there are efforts being made to have a uniform boiler law in force all over the Dominion and there is reason to suppose that within a decade we will see a uniform boiler law in force all over the American continent.

Stanley Shupe, of Oshawa, has been appointed as city engineer of Kitchener, Ont., at a salary of $2,500. Mr. Shupe has had considerable engineering experience in Toronto and Oshawa and at one time was employed in Kitchener. At present he is the engineer at Oshawa

A DAY WITH THE HALIFAX STATIONARY ENGINEERS

BEING an engineer (at least in name) myself and not having any pressing business just at the time I decided to go out and see the plants in the city, or at least as many as I was allowed to visit and have a chat with the boys. As I had not been around much in the last two years, and having very little acquaintance with the engineers of Halifax I was not quite sure that the old password would work, but then I reflected, once an engineer always an engineer, and as I had eaten my bushel of coal dust and ashes like most of them I started out, after having put a plug of Montreal twist in my pocket.

The first place I visited was Camp Hill. I enquired for the resident engineer, Mr. Hobson, Not finding him, I went right into the boiler room and met a cheery, happy-go-lucky fellow from Sydney, who informed me that the chief engineer was not far away. I went around to his office and asked if I could see the chief.

"Right here, sir," sang out a young, gentlemanly looking fellow, who looked more like a doctor than an engineer.

"Well, how's she chuckin' her mud?" said I.

"Divil the finer," said he. "How goes it?"

"Well, it won't fry a spit yet," says I.

We got into conversation right away and when we got a little better acquainted he called his assistant and introduced me and gave me permission to look around.

Well, Mr. Phillips (the chief engineer) has about 300 boiler h.p. at the hospital plant, has a nice little refrigerating plant and a very extensive heating system. The boilers consist of three locomotive type, one R. T. and one water-tube. The boiler plant is far from up-to-date, there being many objectionable features. The present staff are of course not responsible for this as the plant was installed before Mr. Hobson came back from overseas. So they are doing the best they can with a poor outfit.

The firing aisle is about 4 feet wide and the coal is dumped in a storage bunker at one end of the aisle. There is a distance of approximately 60 feet from the bunker to the last fire door. The coal is wheeled in a hand barrow and dumped on the floor. The ashes are wheeled up an incline to a dump outside where they are shoveled into a motor truck. The incline is about 40 feet long and 14 feet high. There is an incinerator situated back of the boilers and the boiler feed pumps are in a well at one corner at the rear. The pumps completely fill the well or pit. If repairs are to be made the repair man must stand on top of the pump or lie flat on the floor and reach down, because there is not room for a man's foot in the pump

A DAY WITH THE ENGINEERS

(Continued from page 42)

pit, let alone room to work. The returns from the heating system flow to the feed pump by gravity. From the points below grade the returns are pumped by an automatic control operated rotary pump.

High pressure steam is generated at the main boilers to operate the laundry and a reducing valve steps the pressure down for the heating system.

The chimney, a concrete one, is about 50 feet above the grates. Owing to the boilers being below grade, the chimney top does not clear the highest point of the buildings. However, as the occupancy of the building is only temporary, Mr. Hobson will not likly undertake any changes. His predecessor got fed up with the job in six months and I don't think Mr. Hobson exactly loves it. It is a pity about the steam plant as the hospital proper is really up-to-date in every other respect.

From here I went over to Victoria General Hospital steam plant. I did not want to go through much red tape so found my way in without looking for a pass. I saw a fellow standing in the engine room door, with a cold calculating look in a bold eye (I did not need to ask for the chief, I could see it sticking out all over him). Well, this was Mr. A. Morash. He was a little suspicious of me when I came around and I think he was still suspicious of me when I left, but just the same I found him interesting and, let me tell the world, that Morash has a few ideas about engineering. He speaks right out in the meeting and calls a spade a spade. On the whole I liked him and I am going to see him again when I happen to be around. He is making some changes in the heating plant and some changes are being made without his approval, entirely, but he was pretty busy and I promised to come again. Morash is assisted by his son, who looks every inch an engineer and no doubt admires his dad.

In the boiler room I met Mr. F. A. Smith, a young returned man with ambition written all over him, in fact the whole engine room staff of this plant looked good to me.

At the City Home "steam plant" I met Mr. Grant, the chief engineer, a fine, quiet mannered man and a very interesting talker. He has a pretty old plant but keeps it in good order. Like his neighbor, Mr. Morash, he is making some improvements to his steam heating system.

I thought I'd seen enough hospital plants for one day, as I was anxious to get down to the tramway power house to have a chin with Mr. Freeman and my old friend, Tom Kelly. But on my way there I just thought of another old acquaintance who is engineer at the Westminster Apartments, Paddy Travers is his name. So I called to see him. Paddy used to be second with Mat Doyle at the Technical College steam plant. They kicked along together for seven years. Mat was chief and is so still, but now Paddy is chief in his own bailiwick. Well, Paddy outdid himself to show me around. He has a new plant, modern in every way, and he is proud of it. Here I made a new acquaintance in Mr. Wakham, who is putting in the steam system. He is a hockey fan. I used to meet him at the games and there we don't wait for an introduction. Wakham says he was just a little disappointed that the Crescents lost out in the League. That, so far as I know, is the only point on which Wakham and I differ. So far I think the Wanderers deserved to win.

Well, I left Paddy Travers and made for the tramways power house. Mr. Freeman was just going out to keep an important engagement, but he received me with a smile, and believe me, Freeman's smile is "some smile," and with it he rules one of the largest power establishments in the East. He is superintendent of power and chief engineer, and can brag of one of the best operated power plants in Canada, both from an efficiency and economy standpoint and continuous service. (An article on this plant will appear later.) Mr. Freeman is ably assisted by Tom Kelly in the engine room and Mr. Fry in the boiler room. I am not so well acquainted with the electrical staff, but the plant operation goes to show that the staff one and all are A1 men, so why shouldn't Freeman wear a smile.

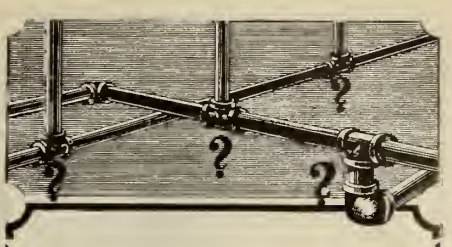
From here I went to see Cummings at the Atlantic Fish Company's cold storage plant. I met Cummings before. He has the only cold storage plant of importance in Halifax, and he sure has a nifty looking proposition. Cummings is a progressive young man with lots of pep, and while his plant doesn't look much from the outside, that old shell covers a bang-up cold storage equipment. Cummings has been chief of this plant for some years though he is only a young man.

From here I went to Moir's factory, where I met Murray Mosher and Theodore Stroude, both of them old acquaintances. Mosher was my assistant in a large plant east of here some years ago. He used to speak of Vincent Scott at that time. Well, I heard so much of Scott that I felt as if I knew him. Scott is the chief engineer at Moir's. So the boys located him where he was busy in another part of the factory, and made me acquainted. My impressions of Scott formed before I met him were that he was a good fellow or he wouldn't be so popular. Well, he is just that.

Scott has a big job and is continually improving the plant and it is easy to see that he knows his business.

MIKE CHROMETER.

Plans are being prepared by Brodeur and Pilon, architects, 63 Hotel de Ville, Hull, Que., for a factory to cost $15,000 for the Ottawa By-Products Co., Montclair St.



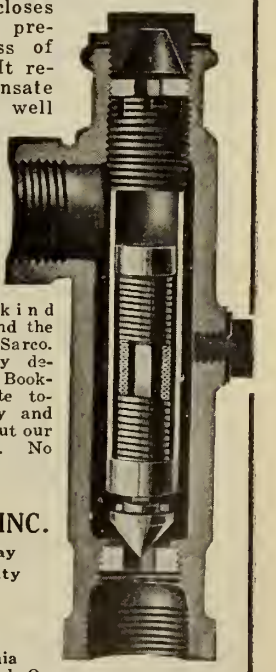
You're Wasting Coal If Your Steam Lines Are Not Thoroughly Trapped!

Because of the high cost of the "bucket" or "float" type of steam trap, many large plants are not equipped with a sufficient number of traps to take care of the condensate properly. A pretty poor policy, and one that is likely to prove very costly with bituminous coal selling at present high prices.

To be properly trapped — and that means economically trapped —a steam system should have a trap at every point where condensate collects.

The low price of the Steam Trap Sarco enables you to buy three traps for the cost of one of the bucket or float type. In that way you can equip your lines with as many traps as are needed, at a low figure, and in that way save many tons of costly coal.

And that is not the only advantage of this trap. Built on the liquid expansion principle, it is free from the complicated mechanism found in other traps—mechanism which will get out of order and cost you money for repairs.



The Sarco closes promptly and prevents all loss of live steam. It returns condensate to the hot well while still hot.

Can be installed without supports or platform.

There are other exclusive features of a money-saving kind which recommend the Steam Trap Sarco. These are fully described in our Booklet J-12. Write today for a copy and information about our free trial offer. No obligations.

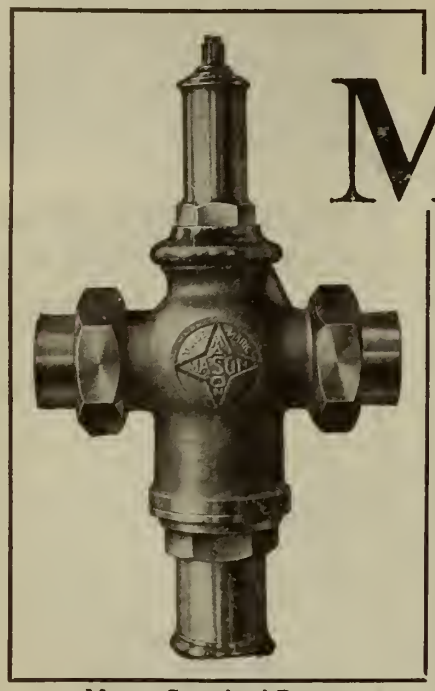
STEAM TRAP SARCO



Mason Standard Bronze Reducing Valve

Let our Engineers help you in your choice of regulating appliances.

Write us for further particulars.

MASON

POWER PLANT EQUIPMENT

For over forty years now, Mason Power Plant Devices have been the standard with careful engineers. Mason equipment, which includes Reducing Valves, Pump Pressure Regulators, Steam Traps, **Reilly Feed Water Filters and Grease Extractors,** is satisfactory because it leaves nothing to ask for in the way of lasting, accurate service.

Toronto: 145 Wellington Street West

Gates Refractories Ltd.

Contractors For

Furnace Linings Firebricks

and Power Plant Refractory Work of every kind. We are able to supply refractory linings of every size and shape. Made to order if not in stock.

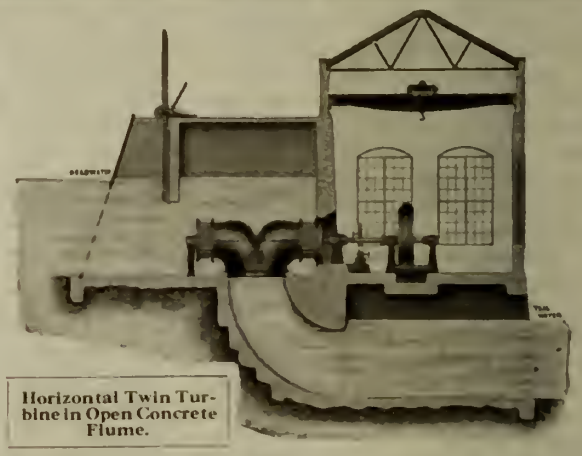
Our linings reduce joints in furnace walls, prevent air leaks, last longer and promote better combustion. Immediate shipment.

We specialize in Boiler Setting, Furnace Building, and Oven Work. Let us estimate.

Experts on Repair Work

Gates Refractories Limited

382 St. James St., MONTREAL



Horizontal Twin Turbine in Open Concrete Flume.

Water Wheels and Hydraulic Power Plant Equipment

We can make prompt shipment on Hydraulic Turbines, Governors, Head Gate Hoists, Stop Log Winches, Steel Feeder Pipes, Trash Racks, Butterfly Valves, Surge Tanks. All equipment guaranteed to give satisfaction.

Send for Bulletin No. 54.

WILLIAM HAMILTON CO., LTD.
PETERBOROUGH - ONTARIO.

BAILEY Boiler Meters

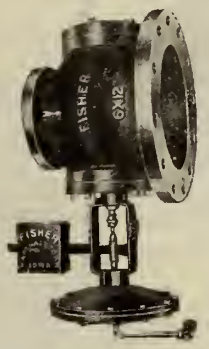
Simple Yet Comprehensive

For efficient operation the Steam Flow and Air Flow records come together and show as a single record. When excess air is entering the furnace, the Air Flow record shows above the Steam Flow. The opposite is true when the coal feed is too great and the fires are not receiving sufficient air.

The record of the Flue Gas Temperature made on the same chart indicates the relative condition of the baffles and tubes. The Fire Box Draft is indicated for assistance in maintaining balanced draft conditions.

Bulletins upon request

Bailey Meter Company
2001 E. 46th St., Cleveland, Ohio



To Meet Canadian Demand

We wish to announce that Fisher Pressure Regulating Devices can now be ordered through your own supply house, dealer or jobber anywhere in Canada.

Fisher Pressure Regulators

have been serving Canadian industries for many years. Engineers throughout the Dominion rely on Fisher Pressure Regulators for accurate, reliable performance and low repair cost.

To the left is a partial list of the many and varied Fisher Pressure Regulators. There is a device for most every purpose.

Partial List of Devices
- *Steam Pump Governors
- *Vacuum Pump Governors
- *Brine Pump Governors
- *Air Compressors.

..*Piston or Diaphragm types with either spring or lever and weight control.

- Reducing Valves
- Tank Controllers
- Back Pressure Valves
- Exhaust Relief Valves
- Steam Traps
- Air Traps

As mentioned above, you can now order Fisher Pressure Regulators through your local dealer or, if you prefer—you can order them direct from our factory. Our large and complete stock insures prompt delivery at all times.

"POWER PLANT SPECIALTIES" tells all about Fisher Pressure Regulators. Write for your copy to-day.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts. It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Write for our catalogue.

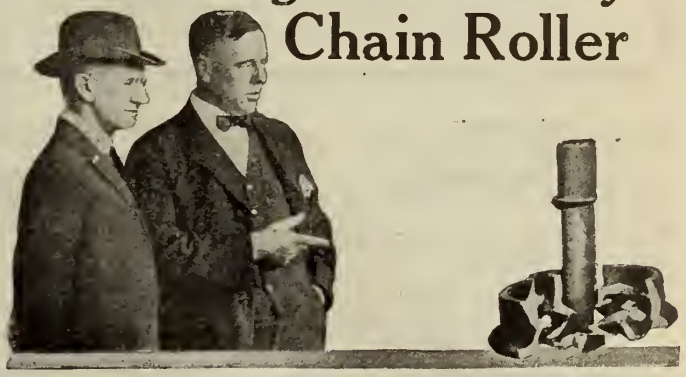
Yes, We Skinned This Tool Steel Mandril In Breaking The Jeffrey Chain Roller



"Before we selected a Pivoted Bucket Carrier for handling our coal and ashes, we made a number of thorough tests and the Jeffrey Carrier showed up fine on every one.

"The Jeffrey people told us that the Chain Rollers were so hard and tough that the bores have to be turned out on a grinder instead of in the usual way of an engine lathe. However, we split one of the rollers with a tool steel engine lathe and were convinced. The case-hardened mandril was actually skinned by the tough metal of the roller."

Showing a Roller being ground on a grinder.

Catalogue No. 210 will tell you about other tests and features that prove the Rugged, Dependable Construction of the Jeffrey Pivoted Bucket Carrier.

in NEW and USED

POWER PLANT EQUIPMENT

You'll find an atmosphere of hospitality throughout Petrie's well-equipped warehouse. Either call or write. You get the same careful service.

Tanks—any size, any capacity up to 2,450 gallons.

Vertical Boilers
1 H.P. to 75 H.P.

Horizontal Boilers
6 H.P. to 200 H.P.

Firebox Boilers—
12 H.P.

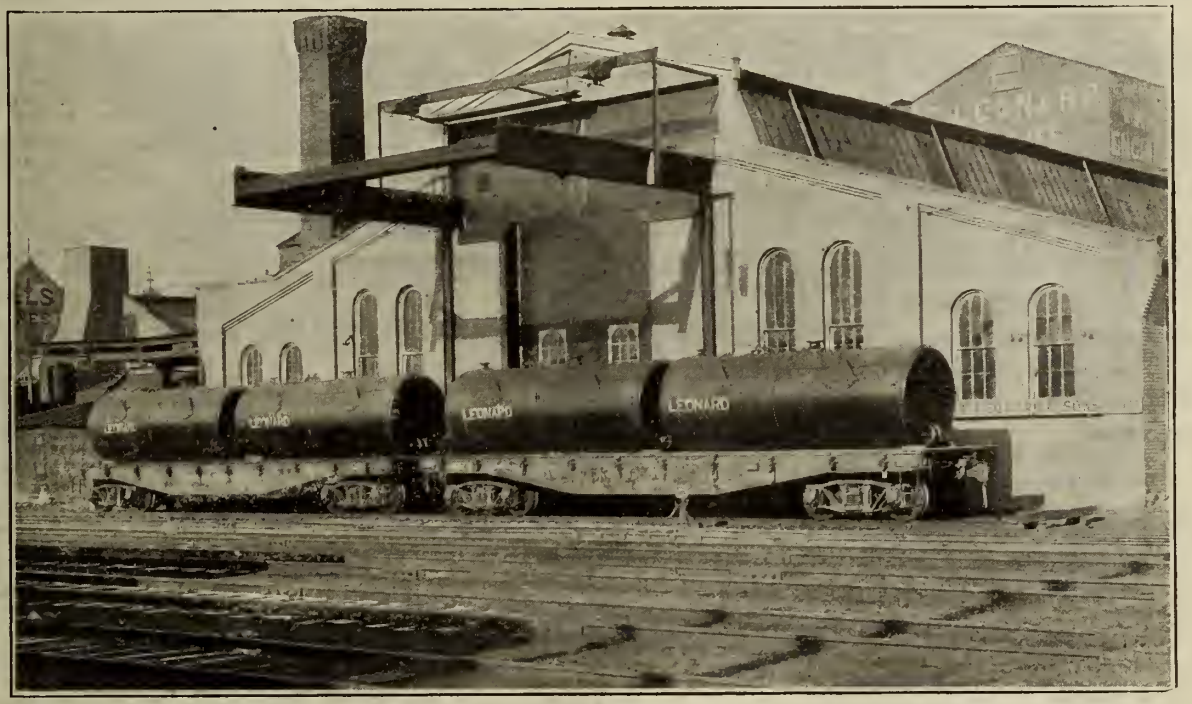
Marine Internal Fired.

Automatic Engines—
15 H.P. to 450 H.P.

Vertical Engines—
7 H.P. to 75 H.P.

Horizontal Engines—
5 H.P. to 40 H.P.

H. W. PETRIE, LIMITED, TORONTO and HAMILTON



Shipment of Four 150 H.P. (72 in. x 18 ft.) Return Tubular Boilers for 150 lbs. working pressure. January, 1921

Established 1834.

Head Office and Works, London, Canada

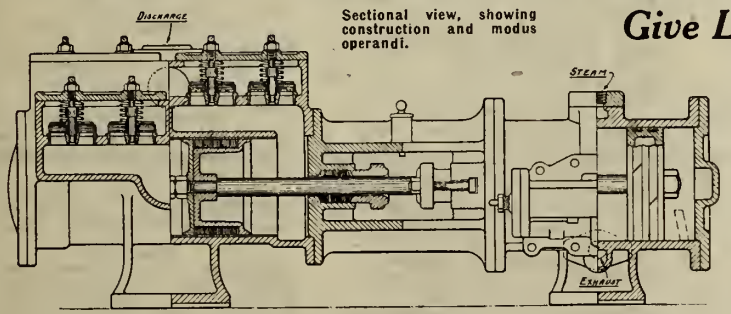
Hepburn Patent Vacuum Pumps

High Pressure Packed Piston Type



Sectional view, showing construction and modus operandi.

Give Long and Continuous Service

Self-draining Steam Cylinders, accessible valves, long strokes, absence of screw threads on Valve Seats and Valve Stops—these are the features that spell pump economy and efficiency. These are the features that Engineers appreciate in Hepburn Vacuum Pumps.

Complete information on request.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

EQUIPMENT

ELECTRIC MOTORS WANTED FOR CASH. Apply, mentioning Power House, to Fisher Electric Co., new warehouse, 77 Front Street E., Toronto, Ont. Main 3288. (pfh)

ELECTRIC MOTORS WANTED FOR CASH. Apply, mentioning Power House, to Henry Engineering Co., 71 Bay Street, Toronto. Adel. 3466. (pfh)

STEAM ENGINES, BOILERS, HEATERS, tanks, stacks, pumps and condensers, transmission and elevating machinery, safes, vaults and vault doors; catalogue and specifications sent on request. Apply, mentioning "Power House," to Goldie & McCulloch Co., Ltd., Galt, Ont. (pfh)

PORTABLE BOILERS—LOCOMOTIVE TYPE, on wheels, each 15 horsepower, with engines mounted on boilers; can get Government certificates for 90 and 100 pounds working pressure; cheap; also 40 horsepower, high speed Leonard automatic engine. Apply, mentioning "Power House," to Henry Engineering Co., 71 Bay Street, Toronto. (pfh)

BELTING

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto. (p.f.h.)

MACHINERY WANTED

EQUIPMENT WANTED—550 H.P. CORLISS type steam engine; 250 H.P. Corliss type steam engine; 36 or 42 Corliss iron planer; wood turning lathe pattern maker's type (all iron); boilers, small and large. The Andrew S. Forman Co., Reg., Room No. 60, 232 St. James St., Montreal, Que.

Chimney Repair Work

Does your chimney need repairing? Experienced chimney foreman and expert repair man is open for engagements. Put your problems up to me. Rates reasonable.
Box 203, Power House.

EMPLOYMENT DESIRED

POSITION WANTED BY AN EXPERIENCED refrigerator engineer, also competent in ice making and electricity. Address, D. M. J., Power House, Toronto. (p1h)204

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers. Corliss and all classes of stationary engines, compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St., Toronto. (pfh)

MACHINIST—WITH DRAUGHTING EXPERIence, wants work of any kind. N. Ryckman, No. 174372, 5 Foxley St., Toronto. Phone Parkdale 3254w. Mention "Power House." (pfh)

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House. (pfh)

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House." (p.f.h.)

Here are the men who place and influence big business. They are the men who read your message when conveyed through the columns of this paper.

The Pivot Men

of Canadian Industrial Activity

THESE men are keen on efficiency, on getting things well done, on saving labor, on saving time, on putting the best into their work and getting the most out of it. These are the pivot men of Canadian industrial progress. They are the men who keep abreast of the times by habitually reading reliable Canadian technical newspapers.

They are the men who buy or influence the buying of the products you market.

If you have a product to sell you can reach these men easily and inexpensively by presenting your message to them repeatedly and intelligently through the columns of their favorite technical newspaper, a publication that commands their respect and attention.

Such a paper must necessarily possess an editorial appeal of the highest order. It must be an authority in its chosen field. It must be free from glamour and pose and bluff.

Technical papers entitled to rank in this class are included in the membership of Canadian National Newspapers and Periodicals Association. Membership in this Association assures the highest standard of editorial ideals—in fact the highest standard in all departments. A careful and detailed analysis of Power House may be obtained on application to the publishers.

Following is a list of worth-while, reputable technical newspapers which are members of this Association and which constitute its Technical Newspapers Section:

Canadian Engineer
Canadian Foundryman
Canadian Machinery
Canadian Manufacturer
Canadian Railway and Marine World
Construction
Contract Record & Engineering Review
Dominion Dental Journal
Electrical Dealer & Contractor
Electrical News
Marine Engineering
Municipal World
Power House
Sanitary Engineer

Canadian National Newspapers and Periodicals Association

Just to again remind you that the

Republic Flow Meters Co. of Canada
LIMITED

will in future be known as

Dominion Flow Meter Co., Limited

The organization has been augmented (retaining the original personnel) to carry on the ever-increasing business, and we trust this change will continue to merit our customers' confidence.

The design of our equipment is in no way changed, and the service will be of the same high standard in the future as it has been in the past.

If ever there was a time when Engineers required the moral and physical support of co-operation with their brother engineers, it is now.

Canada, to-day, after 5 years of intensive production, has been struck by a period of slackness. We are now faced with the necessity of not only not producing at normal rates, but of curtailing the services and expenses so far as it is humanly possible to do.

The engineer has been called upon to do without many things which in his opinion are absolutely necessary, and in many cases he has on his hands apparatus which has largely become unnecessary.

The result of all this is that he must convert the unnecessary to the necessary, and make shift with what he has in the most efficient way. Realizing this, and the necessity for co-operation, we have instituted what we call a Service Department.

This Department, we feel, is fully qualified to deal with any and all kinds of Power Plant problems. Our Service Department will not stop at giving service on our apparatus, but will be glad indeed to co-operate in any way with any engineer who cares to make a call upon this Department for consultation, or service of any description.

In this way we hope to cement the friendship which we have with all our clients, and many who are not our clients, and to be of service generally in this time of reconstruction.

Yours for co-operation,

(Sgd) E. C. Hanson.
Engineer,

With LABRIDE Equipment

Coal Can be Handled at Rate of 100 TONS per hour

WITH ONE MAN HANDLING IT

BY means of moving bridge and cross-travelling trolley the bucket can reach any part of yard within a minute or two.

LABRIDE can serve Canadian plants as effectively as it has in the United States.

Write us for information.

Lakeside Bridge & Steel Company, North Milwaukee, Wis.

How to Test Advertising

THE man who doubts the power of advertising belongs in the same class with the man who refuses to believe that the world is round simply because he can't get off somewhere at a distance and see its roundness for himself.

The merchant who fears to attempt advertising because he figures it as an "expense" is blind to his own interests. I personally know several men who, because they once tried advertising to the extent of a cheaply printed hand-bill and didn't find it necessary next morning to call on the police to keep the crowds of eager buyers from swamping their store, loudly and solemnly aver that "advertising doesn't pay."

Advertising *does* pay.

The most successful merchants are the merchants who believe most thoroughly in advertising and who practice their belief.

But advertising, in order to pay, has got to be *intelligent* advertising.

The day of hashed-over superlatives — "best goods," "lowest prices," "best stock in town," "greatest bargains ever heard of," and so on—has passed.

People have learned to distinguish the *truthful* advertiser from the blatant behind-the-times storekeeper who believes that, so long as *he* claims to have the best goods on earth, or under the earth, or within wireless distance of the earth, people will break their necks trying to get to his counters in the forefront of the crowd.

Put some *brains* into your advertising.

Don't let the office boy write your announcements in between his other duties.

Don't doubt the business-getting and business-building power of intelligent and informative publicity — and you will find that advertising *does* pay.

—Jerome P. Fleishman.

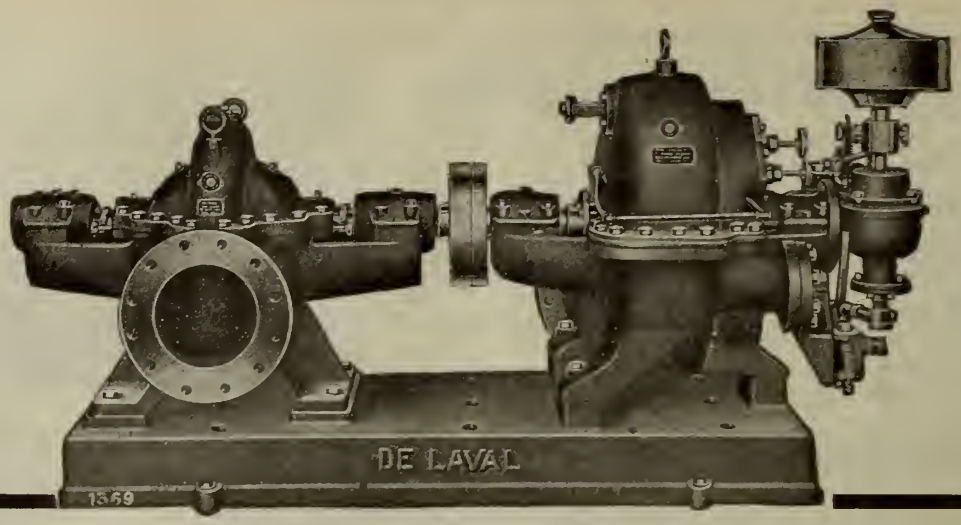
AGENTS WANTED

Practically Frictionless

In Cotton Tubes



De Laval Turbine-Driven Pumps

COMBINED with the De Laval steam turbine, the De Laval centrifugal pump forms a compact, reliable and simple unit, which occupies only a small fraction of the space taken by a reciprocating pump and requires only light foundations or none at all. The turbine and pump are both simple and accessible, and require practically no attention. By providing additional nozzles, it is possible to operate with reduced steam pressure, maintaining full water pressure under conditions where a reciprocating pump would fail.

Describe your conditions, and our engineers will supply full information. Ask for Catalog B-100.

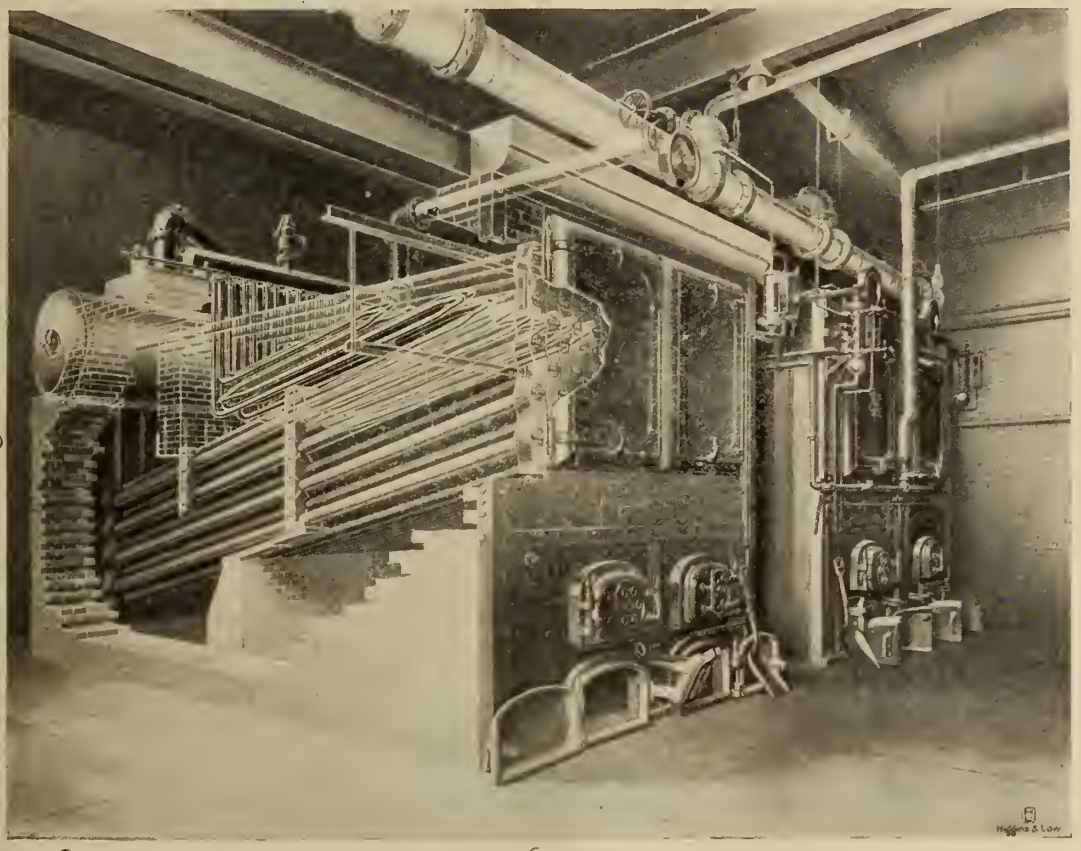
ELESCO SUPERHEATERS



Modernizing by the Application of ELESCO SUPERHEATERS Saves Fuel

MORE reasons exist today than ever before why existing steam power plants should be superheated. While until a few years ago the scrapping of old plants and the erecting of new was justifiable to effect gains in economy, such a procedure today is seldom warranted because of high material and labor costs and because of the recent development of economy increasing factors.

The practical course open is that of modernization, wherein by the application of economy producing factors, old plants may obtain an effectiveness in operation which compares favorably with the most modern plants.

Such a course is practical because the capital outlay involved is small. ELESCO Superheaters are a modernizing factor because their cost of installation is paid for in a few months in the saving they effect in fuel.

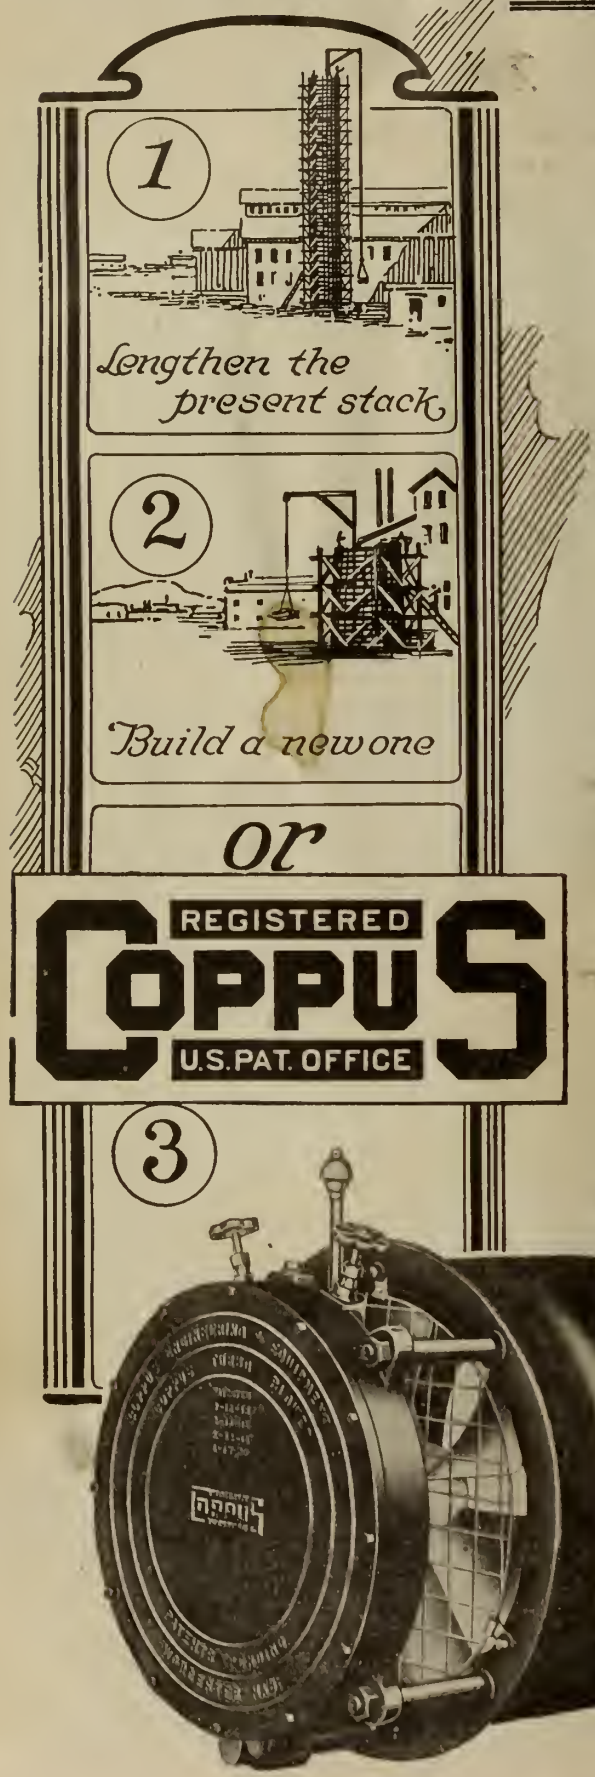
HIGHLY RECOMMENDED BY FIRST-CLASS ENGINEERS

Manufactured by

PENBERTHY INJECTOR CO., LIMITED - WINDSOR, ONT.

For Better Draft—

Which of the three will you select?



1. **Will you lengthen the old chimney with its ever-present element of danger, dirt, confusion—and high cost of labor and material?**
2. **Will you construct an entirely new chimney with its greater cost, loss of time and accumulation of building material, or—**
3. **Will you let the COPPUS Turbo Blower, with its automatic damper and balanced valve control, solve your draft problem once and for all?**

THE COPPUS Turbo Blower can be installed in a few hours' time. It is low in cost, compact, easily installed, and gives positive control of your draft regardless of atmospheric or fuel conditions.

The COPPUS Turbo Blower creates beneath the fire a pressure sufficient to force the air through the fuel bed, leaving to the stack the overcoming of boiler resistance only. It whips new life into your fires and maintains even combustion.

It consists of a single or double stage impulse turbine entirely encased and mounted on the same shaft with a specially constructed propeller fan. Extreme simplicity, fewness of parts, elimination of stuffing boxes, and adequate lubricating facilities, make it foolproof and capable of withstanding dirt, water and rough handling almost indefinitely.

Balance the advantages of the COPPUS Turbo Blower against that of the chimney or any other form of draft producing equipment and see which is the most satisfactory and economical.

The COPPUS catalogue tells an interesting story of better draft conditions. We shall be glad to mail it to you.

Coppus Turbo Boiler Feed Pump

This turbine driven boiler feed pump, built as a single unit, supplies a continuous flow of water without pulsation or vibration.

No valves to be reground, no water plungers or steam pistons to be repacked, no complicated governing devices to be adjusted.

The Coppus Centrifugal Turbo Boiler Feed Pump responds immediately to peak loads and requires little or no attention due to the automatic and dependable lubricating system—that's why so many power plants have installed them in place of more cumbersome and complicated pumping outfits.

We shall be glad to send you the Coppus Turbo Boiler Feed Pump Bulletin also.

Waterous

BRANTFORD, ONTARIO, CANADA

Power & Heating Boilers

Proper steam production is essential in any power mill.

Waterous Boilers enjoy an enviable reputation for easy steaming and for economy in fuel consumption. The correct design of boiler settings is mainly responsible for this.

Whether you are burning coal, screenings, refuse, wood, sawdust, gas or oil, we supply settings that burn it with the least labor and with best economy.

We build Heating Boilers up to 72" x 16', Return Tubular Boilers for power use, up to 165 H.-P.; settings, single or battery, in brick or all-steel.

BOILERS IN STOCK

POWDER-FILLED!

That's the answer in a single word—a word that has come to mean much to power plant superintendents and other large buyers of renewable fuses.

For it is because Trico Renewable Cartridge Fuses are **powder-filled** that they reduce blow-outs 80%, save four-fifths of the money spent for renewal links and keep men and machines busy four-fifths of the time they were previously idle on account of fuse renewals.

Trico Fuses are also "fool-proof," for Trico fuse-links cannot be "doubled-up"—a feature that provides much-needed protection against fire and accident.

Fully Approved by

BOWSER
ESTABLISHED 1885

Gives Long Life to Machinery

Good Lubricating Oil, carelessly stored and inefficiently handled, causes more expensive and less efficient lubrication than does ordinary oil, properly stored, and handled according to modern systems of economy.

A Bowser Stream Feed Circulating and Filtration System will solve your problem and give long life to your machinery. Bowser will also cut your fuel costs. Extensive surveys show average savings in fuel costs of five per cent. where stream feed lubrication is in use as compared with hand lubrication methods.

There is a Bowser Circulating and Filtration System for *your* purpose.

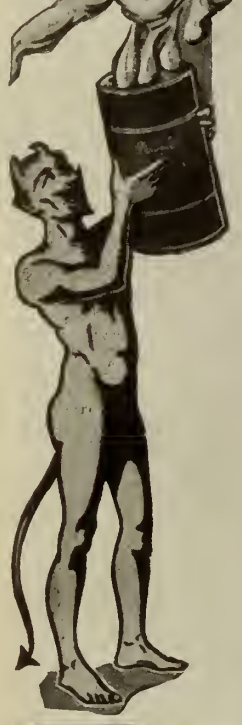
ONE-PIECE
Heat-resisting Furnace Lining
that gives Guaranteed Service

DEVIL'S PUTTY



Plastic, yet when properly baked and vitrified Plibrico—Devil's Putty — shaped into walls, baffles or arches makes one-piece, heat-resisting fire brick as strong as rock and impervious to heat.

Destruction of boiler settings always starts in the joints. Mortar falls out and clinkers find a splendid vacancy to fill. They fuse to the brick ends and when broken off take part of the brick with them. Patchwork repairs are necessary and frequent until finally a new setting is demanded.

PLIBRICO JOINTLESS FURNACE LINING

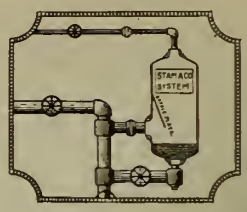
settings eliminate all this trouble. No mortar to fall out—no crevices to disintegrate. PLIBRICO withstands temperature up to 3100° F. Its smooth, jointless surface leaves no place for clinkers to lodge.

If your furnace does not give service it was not lined with PLIBRICO.

PLIBRICO is sold only in large steel containers of distinctive appearance as shown below. Warehouse stocks carried in Montreal, Toronto, Winnipeg, Vancouver and Calgary. Building the setting is a quick and simple task. Our interesting booklet L3 tells just how to do it. Write for a copy to-day.

JOINTLESS FIRE BRICK CO.
1142 CLAY ST., CHICAGO, ILL.

THE STAMACO SYSTEM



Blow-down of boilers is considered a big loss.

Stamaco eliminates blowing down, thereby creates a saving.

Do you realize that every time your engineer blows down your boiler, that 8% to 12% of fuel is wasted?

Stamaco is guaranteed to save fuel and labor and keep your boiler automatically and continuously clean.

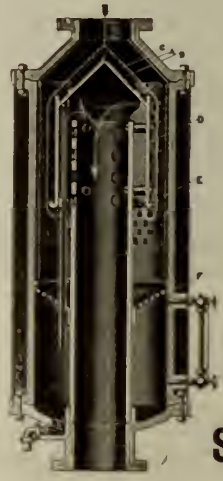
III IMPORTANT THINGS
TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

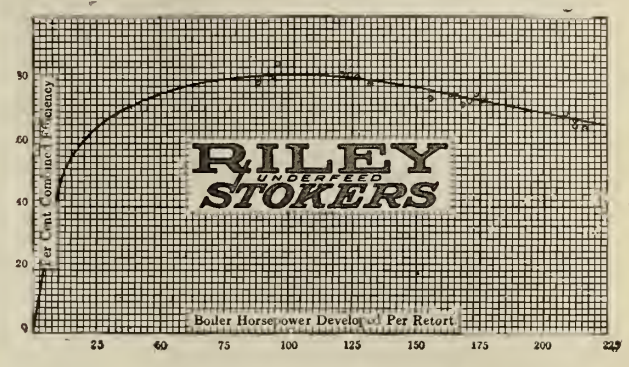
ARE YOU WASTING COAL?



If your boilers are operating at 65% efficiency, whereas you ought to be getting 75% or 80%, then you should investigate to-day the possibilities of RILEY UNDERFEED STOKERS.

The first year after installing Riley Stokers, the Haverhill Boxboard Company saved ten tons of coal a day, and reduced their operating force by thirty-six men—a total saving of $52,000.00.

Our catalog shows a cut of an evaporation curve. From it you can figure just what you can actually save in dollars and cents by increasing your efficiency.

Catalog HR-6 sent on request.

The Heart of Your Power Plant

is the boiler room and there's where all efforts to cut down factory costs must begin. And that is also the place and the reason why you should use

BETSON'S

REG. U.S. TRADE MARK PAT. OFF.

PLASTIC FIRE BRICK

the one-piece furnace wall lining and brickless arch material.

Line your furnace with Betson's Plastic Fire-Brick instead of old-fashioned brickwork which invariably cracks and crumbles and lets in cold air. Then your walls will endure for years rather than a few months; and they'll be free from leaks and cracks, a seal against cooling currents of air.

Boiler arches, too, are readily constructed over simple, temporary sheet metal forms, and after a few hours' heating are all set for regular service. All in one-piece, no bricks to loosen and drop down, they hug the boiler closely as no brick arch ever could.

Betson's Plastic Fire-Brick assures an ideal furnace wall construction, which almost any workman can handle. It means practically a permanent freedom from furnace repairs. Look into it, lay in a supply of Betson's and prevent future boiler shut-downs.

Let us send you our instructive pamphlet about modern furnace wall construction as made possible by Betson's Plastic Fire-Brick. Just drop us a line to-day.

"If it isn't Betson's, it isn't Plastic Fire-Brick"

Which Stoker?

—You Make this Decision Once—It Must be Right

EXPERIMENT with any equipment is costly—but experiment with mechanical stokers is out of the question. The investment is large; it is made once in a lifetime; snap judgment won't do—**which stoker?**

Canadian plants want greater boiler capacity—continuous power day and night when necessary—they want this accompanied by greater economy in burning Canadian coals and by lower labor costs.

This means **high-duty stoker firing,** best exemplified by the Jones "A-C" (Automatic-Cleaning) Stoker.

Regardless of the size of the plant, the grade of coal burned or the local conditions to be met, the logical, safe answer to **"which stoker?"** is Jones "A-C."

The new "A-C" Catalog goes into detail. Jones engineers, with unmatched experience in this specialized field, will gladly make a survey of your plant and give you the full benefit of the best they have learned in installing stokers in many prominent power houses. Investigation implies no obligation.

The Canadian Stoker

Jones Stokers are made in Canada by Canadians, and are sold for Canadian money at par. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been reorganized, and the reorganization makes available for Canadian power users the extensive engineering resources of the Under-Feed Stoker Co. of America.

QUALITY YORK SERVICE

York Semi-Enclosed Refrigerating Machines

The Raw Water Ice Plant is rapidly taking the lead, and its development demands an Ammonia Compressor that is most economical in Power Consumption.

Where electric current is available at a reasonable cost, our Semi-Enclosed Machine, with direct motor mounting, makes a neat, clean and highly economical plant—no belts, no engine or steam lines.

The machine occupies a comparatively small floor space.

All the power developed by the motor is delivered to the crank-shaft of the machine.

These machines are built in sizes from 30 tons refrigerating capacity upwards.

P&H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

SCREWED FLANGES.—For general service, our screwed-on flange gives universal satisfaction and is the least expensive. For steam and water lines, at pressures up to 125 lbs. the flange is screwed home and not refaced. For higher pressure, we recommend screwing on the flange until the end of the pipe projects beyond the face, then refacing by taking a cut across the flange and end of pipe, insuring a perfect joint with the gasket bearing on the end of the pipe. This prevents the pressure from working through the thread of the flange, and insures a long life for the joint.

For all High Pressure service, and where it is objectionable to reduce the thickness of the wall of the pipe by threading, we recommend P&H Lap Joint.

HOMESTEAD Quarter-Turn Valves

Choosing Valves by Reputation

Experience is a great teacher. That is why almost every engineer who has used Homestead Valves will almost invariably tell you that Homestead Valves are the best of all for water, air, steam, gas or acid lines.

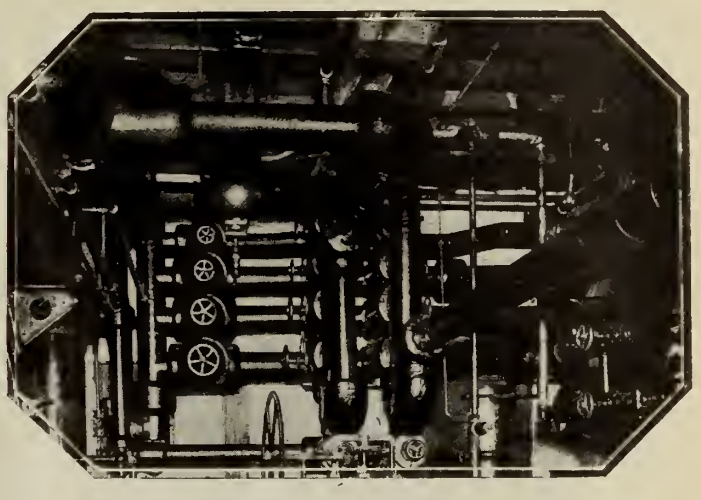
Homesteads are "positive-acting" in each position. When open there is a straight, unobstructed flow. When closed they are positively tight. All Homesteads are constructed with the patented Homestead principle which locks the valve tightly to the seat when closed.

One quarter of a turn only is necessary to open and close Homestead Valves. Adopt them. You'll save time, trouble and expense.

Catalog upon request.

Homestead Valve Mfg. Company

Pittsburg, Pa. *Works:* **Homestead, Pa.**



How the Hill Top Ice Co., Pittsburgh, guards against loss of refrigeration from these ammonia lines and manifolds with Nonpareil Cork Covering on pipes and fittings.

Figured in Tons of Ice

Assume in your plant 110 feet of 3-inch ammonia suction line carrying gas at 8° F. through an average air temperature of 75° F. If uninsulated, such a line loses one ton of refrigeration per day—the equivalent of a half a ton of ice. On the basis of six months' operation throughout the year, the loss from this one line is 90 tons of ice, which, at $4.00 per ton, is $360.00.

Nonpareil Cork Covering on brine and ammonia lines effects a saving of approximately 80% of bare pipe losses. Hence, insulating this line with Nonpareil Cork Covering, Standard Thickness, means saving $288.00—an annual return of well over 100%. In other words, Nonpareil Covering pays for itself easily the first year, and because of its remarkable durability, will continue to pay that high return for many years after.

This is one of the reasons why, in modernly-equipped ice plants, the brine and ammonia lines are insulated with Nonpareil Cork Covering.

For any size or length of line you can easily figure the loss and saving from the tables given in the 64-page book, "Nonpareil Cork Covering." Much other information of interest and value to the users of mechanical refrigeration will be found in this book, which, on your request, will be sent you free of charge.

PUTS AIR TO WORK

AIR WASHERS

WILL DISCOUNT YOUR GENERATOR REPAIR BILLS

Decreased profits are often the direct result of increased upkeep costs. Where generators are in service much can be lost or gained according to the attention given to their ventilation. Neglect in this respect means losses of money, time and labor for inevitable and frequent repairs, while the employment of a reliable air washing apparatus will give extra profits, eliminate shutdowns, give greater capacity and longer life to the generators.

Sturtevant (TRADE MARK) **AIR WASHERS AND COOLERS**

are a paying investment from the start. They successfully keep the generators free from dust, oily vapors, dirt and ashes, and keep them clean and cool.

With many modern washers the cleansing of the nozzles is a long and expensive job. A full day's labor is required, for each nozzle often has to be taken out and cleaned separately at the work bench. With the Sturtevant nozzle the process is easy. Simply remove the nozzle caps, then turn on the water and let them flush out. Three-quarters of an hour is all the time it takes. Clogging is prevented by the large orifice on the nozzle.

The washer is solidly and rigidly constructed; it is also supplied with a bronze fitted centrifugal pump.

The fact that washers for 250,000 k.w. were sold in one month shows that they are worthy of your consideration. Our catalog **226U** describes their various sizes and advantages. Send for your copy now.

Save 70% of Your Coal Handling Cost

LABRIDE COAL HANDLING EQUIPMENT

The Most Economical for the Power House

IF you are unloading coal by hand the Labride Equipment will save you from 70% to 95% of your coal-handling cost. This equipment consists of a moving bridge travelling lengthwise of the storage space and a bucket carrier travelling crosswise. Thus, every square foot of storage space is covered with a minimum of movements and time. The Labride Equipment is the fastest, most efficient and economical method known in coal handling to-day.

3 Big Advantages

1st—Economy. This bridge will in addition save you 25% to 50% if you are using mechanical methods of handling. The saving per ton is greater the more coal you store.

2nd—Eliminates shut-downs due to strikes at the mines, railroads, or from failure to receive regular commitments of coal due to transportation congestion.

3rd—Saving money by enabling you to lay in your supply of coal in the spring and summer months when coal is generally cheaper than it is in fall. This item runs into quite an amount in case of large coal users.

A sketch of the equipment best suited to your needs will be forwarded on receipt of a layout of your storage yard.

Coal can be unloaded from cars to the bunkers or to the storage pile. Our No. 2 bridge, shown in the illustration above, is electrically operated throughout and has a guaranteed capacity of 60 to 90 tons per hour. The cost of the electrical current is about 60c per hour. The entire unloading operation is handled by two men—one man in the cab and the other in the car cleaning out the corners.

New Truths and Old Fallacies

Hardness of Alloys—*Continued*

Charpy says that a lead-antimony-tin alloy is superior to a lead-antimony alloy, as tin strengthens the eutectic, but as to whether this adds to the malleability as well as to the hardness, we do not know.

Another hardening medium now being used to some extent is Metallic Sodium.

A mixture of lead, said to contain only 2 per cent. Metallic Sodium, is being offered as a substitute for babbitt.

Our experience with this element is that it is highly volatile and oxidizable and it is said to be very unstable. As a protection against the heavy fumes, this mixture has to be made in a closed kettle and the metallic sodium held beneath the molten lead to prevent its dissipation and oxidation from atmospheric influences. It is also claimed that chemical action takes place, which changes mixture to an oxalate of lead, particularly if exposed and that the men handling it have to be specially instructed in its use and protected from the fumes.

We understand that it cannot be used over again, to advantage, that its value is lessened as scrap, and that it cracks from shrinkage unless secured by dovetail recesses close together and is difficult to pour a casting free of blowholes; also that the U.S. Government found it unsatisfactory.

The compression test figures shown herein do not inspire confidence in copper as a hardening medium, nor in the belief that tin base metals have any preponderable superiority in that respect over lead base metals. Were it not for the slightly superior malleability of Genuine Babbitt, there would be no valid reason for its use at all and from the beginning it has been displaced by Magnolia in bearings of all descriptions, where the use of Genuine had been deemed imperative.

DEPENDABLE SERVICE AT WINDSOR WATER WORKS

IT is a significant fact that Rees RoTURBo Pumps are chosen where efficiency under varying conditions of load is required. This fact is attested by the above illustration which shows two Rees RoTURBo Pumps giving steady, day-in and day-out performance at the Windsor, Ont., Water Works. Rees RoTURBo Pressure Chamber Pumps, Rotary Jet Condensers and Rotary Air Pumps are demonstrating their dependable qualities the world over in Mines, Power Stations, Marine Service, Water Works, and all kinds of Industrial Plants. Our catalogues will be forwarded to parties interested.

Overhauling and Adjusting in the Engine Room

In This Article the Subject of Pumps is Carried Further, and General Construction of the Water End and the Method of Packing Explained

By "FITTER"

IN cases where the seats of valves in the water end of pumps require some facing up, which is not enough to necessitate taking out the individual seats or the deck, they can be faced in place. If the valves are of brass the best way is to mount the valve on a temporary spindle and grind valve and seat to each other with powdered emery. When the valve seats only are brass, an iron plate of the same size as the valve can be used. This plate can be mounted on a spindle and is of course faced up in a lathe. The brass being softer than the iron will of course wear down to a face without injuring the iron plate. A correspondent in this issue mentions facing valve seats down with a piece of smooth file, finishing off with a file ground to a scraper edge. If a man is trained in the efficient use of a scraper he can face the seats up by this means alone, but unless he has good experience with using a scraper he may likely make the last state worse than the first. With flexible rubber valves, there is a good deal of leeway permissible from a perfect face on the valve seat.

Pumps fitted with special types of valves, such as the Kinghorn valve used in the "Weir" pump, or some types of air pumps, generally give little trouble as far as the seats are concerned, and when the discs themselves show signs of wear are easily replaced. These valves are simply flat discs of thin bronze of special composition, mounted one above the other on the valve spindle, with the lower disc the same size as the seat and the next one somewhat smaller, while the top one is smaller again. Owing to their lightness and the fact that a certain amount of water gets between them to act as a cushion, they work with very little shock, and last as a rule much longer than the ordinary kind of valve.

The Piston or Plunger Pump

Reciprocating pumps are divided into two general classes, inside and outside packed pumps. The inside packed pumps are the piston type, while the outside packed are the plunger type. Occasionally one finds a pump which is a combination of inside and outside packed, that is a piston plunger pump, but there are not many of these kind knocking about nowadays. They used to be rather plentiful in certain classes of marine jobs, but I have not come across any in stationary practice.

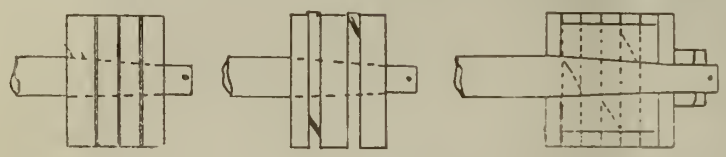
The piston pump has in most cases a packed piston, that is a piston made up of a main body with flange cast on it, and a follower plate which holds the soft packing in place. Sometimes a piston pump is made without any packing, the piston being made to fit the liner closely, and water tightness being secured by turning narrow grooves in the body of the piston, which form a water seal. In other types, rings of special composition are fitted in the piston in the same way that the spring rings are fitted in the steam piston, and this is a very satisfactory construction. The plunger pump has no packing at all excepting that in the gland through which it works at the front end of the pump, and this is the easiest type to pack. We will just go over the work connected with these different types and see where the advantage or disadvantage of either lies. Engineers differ considerably in their opinions on these points, and as in many other engineering matters, it largely depends on the individual experience one has had which way the preference is likely to go.

The Water Piston

In the usual type of piston pump, the piston works in a brass liner which is fitted into the barrel of the pump a tight fit, usually known as a drawing fit. That is, it is usually forced to its place by being drawn down with a plate and long screw as shown in the sketch, and removed in the same manner. In order to make it absolutely secure, a ring is fastened over the mouth of the liner by a number of set screws, a water-tight joint being made between the liner end and the ring. It is essential that the liner be a tight fit in the barrel of the pump, otherwise water will be passed from one end of the liner to the other between the pump casting and liner and a loss of efficiency result. This is not a very common occurrence, but I have known it to happen when a new liner has been fitted to a pump by careless machinists. When having repairs made by the machine shop for any part of the engine room machinery, always give it your personal attention. There is a real necessity for this, especially when the machine shop is in your own factory. They are apt to look on engine room work as something to be got rid of as soon as possible, and if not carefully watched and impressed with the importance of the part being made right, will not give it the care that they will when making a jig or tool for production purposes. Further, and perhaps the main reason for any carelessness on their part, is the fact that they in very rare cases have any realization of the importance of the duties the piece may have to perform, and the troubles that may ensue to the operating force in the engine room. Therefore don't take anything on trust as far as the machine shop is concerned.

The body of the piston is fitted on to the piston rod, which is usually of brass or bronze composition, a taper fit, with a shoulder at the end of the taper in the beter made type of pump. This body may be solid, as in the smaller sizes, or hollow with ribs supporting the spider on which the packing is fitted. The piston rod extends through the body of the piston far enough to give support to the follower plate which holds the packing in position, and for the nut and jam nut which holds the whole together and on to the rod. The packing is as a rule a square fibre packing, of which there are a number of good brands on the market.

The method of packing will depend on the engineer, there being two ways. One of these is to take the packing, scarfing one end so that it will lie square up against the flange, and wind it round and round the body of the piston till the packing space is filled up, the back end being again scarfed to fit square up against the follower plate. The second method consists of cutting one ring at a time, and either scarfing the ends or butting them, leaving a small opening for expansion. Both these methods have their exponents, but personally I prefer the single ring method. When the packing is laid on the piston in a continuous spiral, it forms a solid and compact mass when tightened up, and there is no opportunity for any give or adjustment. This is the feature that those who use this method claim is an advantage. However. it allows no chance for the packing to expand, and therefore puts a severe strain on the packing itself, and also makes the friction on the liner much more severe, without gaining anything in water tightness. There is another disadvantage and that is that when any wear occurs the whole of the packing must be taken off and replaced.



Types of Pistons

If the packing is laid on ring by ring, staggering the joints and leaving about one-eighth to three-eighths between the butts acording to the size of the pump and the known tendencies of the packing, there is a chance for a little adjustment all round when the pump is working. A certain amount of water can find its way into the packing space and act as a lubricant. The spaces between the butts allow room for expansion, and there is less friction. This makes for longer life to begin with, and as it is the end rings that get the worst of the wear, these can be replaced without taking the middle rings out, and after a while they can be used to replace the middle rings, new rings being put in the place of the end ones. This tends to cheapen packing expenses.

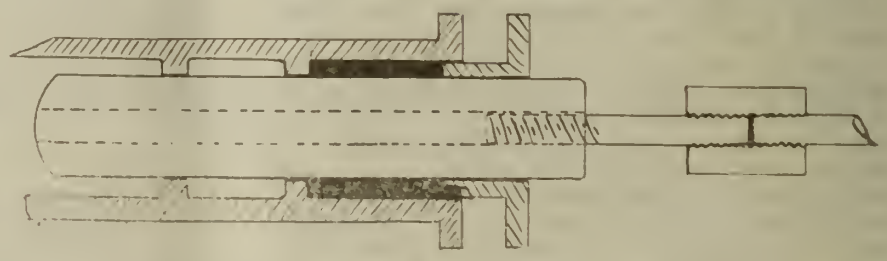
With every pump there is furnished a box spanner for the purpose of taking off and tightening up the piston rod nuts. This spanner should be carefully preserved and used for nothing else but that pump, and nothing else should be used on the piston rod nuts but the spanner made for the job. Too often, one finds, when the cover is removed from the water end, that the piston is held on to the rod by two shapeless pieces of metal, hammered and battered out of all semblance to the nuts they once were, and only capable of being removed by a further application of the hammer and caulking tool or chisel. There is no need of this. It is easier to use the tool made for the job, and if there is any difficulty in slacking off the jam nut without moving the two nuts together, hold the inside nut with a crow-foot spanner or a flat spanner offset to go inside the box spanner. Don't slack the two nuts off together, as in doing so you run a good chance of hurting the thread or even twisting off the end of the rod. A little care in this direction will save a lot of time when overhauling is necessary, and if you ever have to do a job of packing in a hurry, you will be glad you took care of the nuts and spanners.

When starting the first turn of packing always put it under the piston first, as this will lift the piston up into the centre of the liner. If the packing is put in the top first, and the piston is lying down in the bottom as it is most likely to be, this makes it all the more difficult to get the packing round. After the first turn is on it will of course not matter which position the second ring is introduced in.

When actually putting the packing on the piston, make sure that each individual turn, or each individual ring, goes hard up against the flange, first, and against each other after the first one is in. Tap them up all round a little at a time, till you know by the feel of the packing stick when you strike it that the ring is solid. Don't stick it in anyhow because you are in a hurry. In doing any job on a piece of apparatus that has to be opened up and closed up again before it is ready to work, remember that the more haste the less speed. Don't waste time, but don't try to save it by scamping the job, because if you do you will have to do it over again. You young engineers just starting up the ladder will find that when the chief discovers a man whose work he can rely on, that man will not be long before he works up. No chief likes to have a man whom he has to watch or who will report a job done when it is only half done. He has generally enough to occupy his mind without having to watch every turn of packing that goes in or every nut that is tightened up. This may sound like preaching, but there are quite a few gray hairs in my head caused by subordinates who assured me they had done a good job, when in their hearts they knew they had not.

When all the packing is in, put on the follower plate, and tighten up the nuts. In small pumps the follower plate is merely held by the nut that holds the piston on to the rod, but in larger pumps the follower plate is held by set screws screwed into the body of the piston. In any case, tighten up the follower plate to its working position, but before you put the jam nuts on the rod make sure that your piston is not too tight in the liner. You should be able to move the piston up and down in the liner the full length of its stroke by means of a bar, without undue effort. A small pump of say four inches bore should be moved easily with a bar 18 inches or two feet in length, while the large sizes will require more leverage. However, pumps up to twelve inches should move easily with a bar not more than four feet long. Of course, this refers to horizontal pumps. If the piston does not move fairly easily, then make sure what is holding it. If the packing is doing it, find out if there is too much in, and if so it may be necessary to use more rings of a slightly smaller diameter, or cut the end ring in two lengthwise to make it narrower. Don't run a pump with the packing too tight, for it will only cause undue wear, and you will have to repack it so much sooner, besides putting an extra strain on rods and all working parts. Remember that most packing swells to some extent until it is saturated, and if you start with the packing unduly tight it is going to be worse after a while. On the other hand, don't have it too slack or it will flop about and rub on itself, causing just as much wear as if it was too tight.

With the solid type of piston there is of course no question of packing. The only thing to do when this piston gets worn or, as usually happens, the liner gets worn is to bore the liner out and fit a new piston. However, I have seen a temporary repair on a piston of this kind that lasted so well that it was made practically a permanent job. This was a small duplex vertical pump, with solid pistons, having two water grooves turned in each. These had in course of time worn slack, and as there was no chance of replacing them immediately, some means of keeping the pump going in a fair state of efficiency was necessary.



Section of Plunger Pump

The method adopted was to turn the water grooves deeper and wider, and to fill them up with white metal, leaving the metal projecting above the surface of the piston. This was done in the ordinary way of making a mold and pouring the metal in. The rings were then scraped up to fit the bore of the liner, and the job was so successful that the white metal was worn down and refilled several times before the pump was fitted with new pistons.

In the case of pistons fitted with rings, whether composition or otherwise, the usual way of effecting a repair when the proper rings are not available is to make rings out of Muntz metal or other suitable bronze. A sheet of ½-inch Muntz metal is a useful thing to have around, and although in the case of a power plant situated close to a source of supply this might not be needed, in more or less isolated plants it often is.

A strip of metal is cut long enough to bend round in the form of a ring, and of course larger in diameter than the bore of the liner or cylinder. It is scarfed at the ends in the ordinary way and fitted into the cylinder just as a cast iron ring would be. This is not by any means an unusual thing, and I have seen steam piston rings made in the same way and serve their purpose for quite a while. Of course, one would expect in a stationary plant that spare rings would be on hand, so that there would be no necessity of making temporary expedients, but there is no harm in knowing that it can be done.

The Plunger

Coming now to the outside packed or plunger type of pump, we find quite a different method of construction. Here we have no packing inside the water cylinder at all, and no liner such as we have in the piston pump. Instead, all we have is a narrow ring of metal in which the plunger slides, and at the outer end a stuffing box and gland to take the soft packing. The weight of the plunger is carried on the packing in this gland for the most part. The packing being entirely outside the cylinder gives the pump its description of outside packed. Practically the only trouble with these pumps is the wearing of the packing and the plungers themselves. Packing is easily renewed. The plungers are connected to the piston rod by a crosshead into which they are screwed and held by nuts. The pumps are made in simplex and duplex styles, and are either end packed or centre packed. The plungers are of course single acting, so that there must be two plungers in separate barrels to give continuous delivery. These cylinders are arranged either with their ends abutting and the plungers working out at opposite ends, or with the cylinders facing each other and the plungers made in one piece for both barrels. In the first case the plunger farthest away from the steam piston is worked by extension rods from the crosshead of the inside plunger. In the latter type the piston rod is continued through a small stuffing box and is screwed into the plunger, which of course is one piece. There is one advantage about the outside packed pump and that is that there are few moving parts, the packing is easily got at, and the wear takes place on the packing only. On the other hand, the heavy plungers induce rapid wear on the packing, and some trouble is experienced with glands breaking through the construction being not well designed. These glands are usually only fitted with two studs, and as often happens the inside one is difficult to get at when the pump is working, the outside one gets all the tightening. This results in broken glands in many cases. The main thing to watch with an outside packed pump is to get a good grade of packing, pack the gland evenly, and repack it when the packing shows signs of wearing or getting hard. Don't try to stop a badly leaking gland when the pump is working and the packing is hard. It usually results in trouble. When the plungers wear they have to be renewed, and when they are renewed care must be taken that they are not made too heavy. If they are procured from the maker there will be no trouble about this, but if made by the factory shop or a local foundry they may be unduly heavy. Also take care if made locally that the core hole in the plunger is tightly plugged before the plunger is fitted. If water gets in there it will lead to a considerable addition to the weight of the plunger, as well as a lot of useless work for the pump.

We seem to have found quite a lot to say about pumps, but we have by no means exhausted the subject. Probably this will help to make the young engineer understand that it takes time to become an engineer, even if this term is only applied to a good practical man, leaving the theoretical end strictly alone.

(To be continued)

GRAPHITE

One of the non-metallic minerals with which the public is more intimate is graphite, otherwise known as plumbago or black lead. It is a soft, dark grey, opaque solid, of a greasy metallic lustre found in detached masses, beds, crystals and sheets. Ceylon is the chief source of the world's supply of graphite, but it is also produced in Canada, England, New Zealand, Siberia, Germany and the United States. In Canada it is found in Northern British Columbia, in Eastern Ontario, in Ottawa, Argenteuil and Pontiac counties in Quebec, in Carleton, Charlotte and St. John counties in New Brunswick, and in Cape Breton, Inverness and Halifax counties, Nova Scotia.

Graphite occurs usually in the fissures or veins of granitic or similar rocks, but is also found as isolated plates, patches and pockets in what are known as bedded veins. It is commonly associated with quartz, calcite and mica, according to the rocks in which the graphite occurs.

The crude graphite must be very finely ground, to detach it from associated minerals, after which, by a concentration process, it is separated from the accompanying mineral particles. It is very carefully graded, both as to fineness and purity, to eliminate particles of grit.

Graphite is best known through its use in the manufacture of lead pencils. For this purpose it is mixed with clay, moulded into shape and baked. The proportion of clay used regulates the hardness of the pencil. For pencil-making the best graphite is secured from Borrowdale, Cumberland, England, and Batugal, Siberia.

Other uses of graphite are in the manufacture of stove polishes, and paints for ironwork, of crucibles for the casting of metals, and of electrotypes. As a lubricant graphite is used, both in dry form and mixed with grease or oil, in many industries where heavy work and high speed are required. In foundries it is used in facing moulds to give smooth-finished castings. The electrical industry is using large amounts of graphite. and in the manufacture of gunpowder it is utilized as a moisture-proofing material.

Canada produced 2,227 tons of graphite in 1920, valued at $173,537, as against 1,360 tons in 1919, of a value of $100,-221. In 1920, Quebec contributed 233 tons and Ontario 1,994 tons, while in 1919 almost the entire output was from Ontario.—"Conservation."

DOMINION STEEL PRODUCTS COMPANY EXPANDING

The Dominion Steel Products Company, Limited, whose main office and factory is at Brantford, Canada, have just opened a sales branch at 418 St. James Street, Montreal, to handle Dominion light plants, as well as pulp and paper machinery, rolling mill equipment, Dominion chucks and other articles this company manufactures.

This company has just arranged to manufacture in Canada the well-known Darling valves and Darling fire hydrants.

Their new Montreal branch will be in charge of Mr. Maurice P. Shea, who has had many years' experience in the machinery, valve and engine business. Mr. Shea for four years was overseas in command of a submarine chaser.

AN ANONYMOUS CORRESPONDENT

We have received a letter of criticism from a correspondent who, however, has neglected to give any name or address. We shall be glad to receive these, not necessarily for publication, but as a guarantee of good faith. Anonymous letters are not entitled to any consideration, but genuine letters of criticism from readers will be published just as quickly as letters of commendation.

Power Plant Instruments and Meters

The Operating Engineer Now Has Available a Much Greater Number of Helpful Instruments Than His Predecessors—Some of Them Are Classified Here and Their Uses Explained

By E. G. BAILEY*

INSTRUMENTS and meters are used in the power plant to visualize operating conditions for the purpose of obtaining better efficiency and capacity.

In the past the question of capacity has been emphasized more strongly than has efficieney, and it is a matter of prime importance, for the man who maintains a high capacity with every piece of equipment in the power plant is doing the work with a smaller investment and a smaller overhead charge than the man who is letting the boilers and generating equipment drift along at a lower rate and a poorer load-factor.

While instruments and meters have been used extensively in power plants, they were largely confined to test work where they were in the hands of an experienced engineer who carefully calibrated and checked up all apparatus before and after the test. Such instruments were practically all indicating, and readings were taken at intervals of time throughout the test.

For a long time the operating engineer had nothing to visualize his operating conditions except a pressure gauge, a water glass, and the steam-engine indicator. Later, the ordinary thermometer came into general use, and a little later the recording pressure gauge and recording thermometer found their way into the power plant, and their use has been gradually extended until they are to-day very prominent as power-plant instruments, and are serving a good purpose in a variety of uses.

Classification of Instruments.—In comparatively recent years many additional instruments and meters have come into common use. These may be divided into three general classes:

1. Instruments to show condition (indicating and recording): (a) Pressure; (b) temperature; (c) humidity; (d) quantity.

2. Meters to indicate or record rate: (a) Steam flow; (b) water flow; (c) air flow; (d) stoker speed; (e) fuel supply.

3. Meters to show relation: (a) Steam flow, air flow, fuel supply; (b) energy input, work output, turbines, pumps, etc.

The instruments of the first class apply particularly to fluids and material, showing the state or condition of these. Pressure and temperature are the most common factors. Temperature, for instance, is a measure of heat potential showing the state of molecular activity. Pressure is a state of molecular compression. Quantity is used in a varied sense; for instance, a level gauge showing the amount of water in a boiler or the amount of coal in a bunker. Integrating meters which show the total quantity up to a certain time also belong to this class.

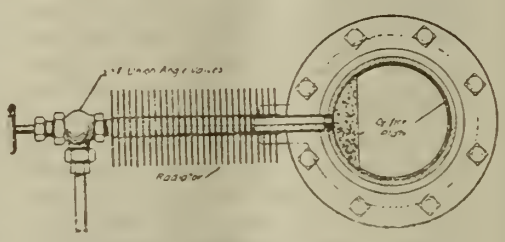


FIG. 2.

Meters which indicate or record rate are extremely useful in the power plant. We are all familiar with the rapid development that has been made since the venturi meter was first used as a means of measuring feed-water. Later forms of flow meters have been developed for measuring steam, gases, oil, etc.

The third item, covering meters which show relation, is the most recent and most important development. The first two classes of instruments and meters give results that are as a rule of limited value until they are associated or compared with certain other results. For instance, a boiler may be generating a great deal of steam but doing it very inefficiently with a high flue-gas temperature. It is therefore desirable to correlate certain factors which are properly associated so that the operating engineer can see whether or not the best operating conditions are being maintained.

Indicating v. Recording Instruments.—The question of installing indicating rather than recording instruments is one which most frequently comes up for decision. It has usually been considered that the recorder had its principal advantage in showing the chief engineer or boss what was taking place throughout every hour of the day or night. This is a distinct advantage, and is sufficient to decide the matter in most cases. There is also the further advantage that a great deal of valuable information can be obtained from different types of meters and working out therefrom important engineering data. The principal advantage of recording meters over those which indicate only, lies in the fact that the fireman or the operating man has the chart record before him at all times, enabling him to note whether or not he is maintaining uniform conditions. Recording instruments show in what direction and at what rate conditions are changing, and, for this reason alone, recording instruments have a decided advantage over those which are indicating only.

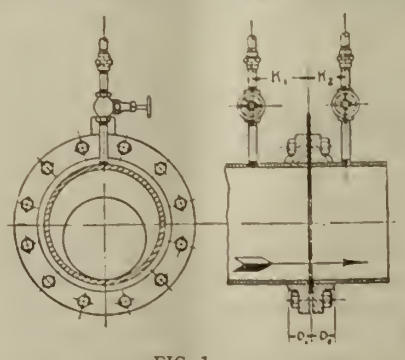

FIG. 1.

Accuracy and Care of Instruments.—One of the first and most important points to be considered in connection with instruments and meters is their initial accuracy and their reliability in maintaining this accuracy. Unless the readings are reasonably accurate they are worthless.

Many instruments and meters installed in power plants have been of little or no value because the operating engineer failed to give them proper attention. The operating engineers who do not produce value from instruments and meters may be divided into three classes:

First, the man who is entirely unfamiliar with meters and instruments and who is afraid to touch them for fear he might damage them. Second, the one who fears nothing of this kind and does not hesitate to take any instrument entirely apart without reading instructions. Third, the one who is too busy to pay any attention to the instrument or meter. Often, in case of failure or inefficieney, a meter may be showing him exactly what is wrong with his plant, yet he is not sufficiently acquainted with its readings to interpret the results indicated.

The real solution is to place the power-plant instruments in the hands of somebody who is thoroughly familiar with them. The duties of this man are threefold: First, to make sure that the instruments are in proper adjustment. Second, to interpret correctly the readings and to instruct the fireman and operating engineer how to obtain the desired results. The third function of this "results engineer" is to calculate, plot and tabulate the results in such a form that he can keep a reliable check on all equipment so that he can recommend improvements.

There is a real field for such men, and their efforts are going to be appreciated by those who are controlling the financing of power plants and industry.

Flow Meters.—Of the second class of

meters, as also of the first, there is a very general knowledge to-day, but in regard to the orifice type of flow meters there are a few points that are not fully understood by all power-plant men. These it might be well to explain briefly.

The sharp-edged orifice has been calibrated and used a great deal for measuring water and air flowing from tanks and reservoirs, usually designed for high-pressure differentials. Its successful use in pipe lines was limited, however, to very low capacities, or, in other words, to cases where the ratio of orifice diameter was small. Those who first used the thin-plate orifice between a pair of pipe flanges for measuring flow of fluids at high velocity found very discordant results. Subsequent experiments have shown that this was due to the fact that a great deal depended upon where the pressure connections were made; the principle was the same as with the venturi tube.

Fig. 1 shows an orifice located in a

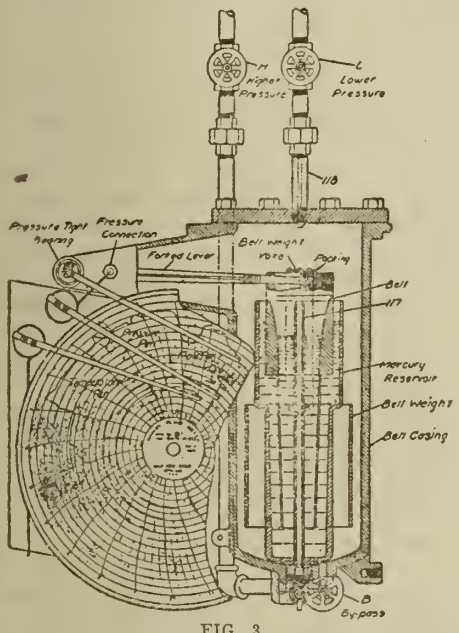

FIG. 3.

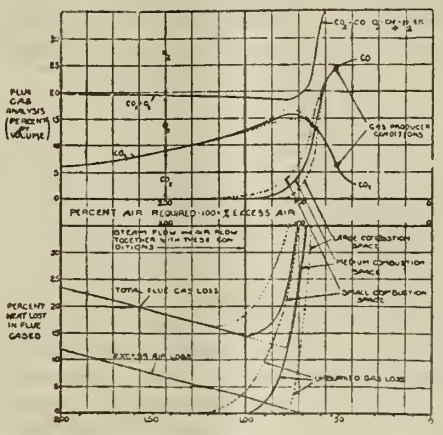
horizontal gas line. The opening is circular, but eccentric with regard to the pipe, so that the hole is flush with the bottom of the pipe with no chance for condensation to accumulate. The pressure connections are taken out from the top of the pipe, and may be connected to any form of indicating or recording meter.

A similar type of orifice is used for measuring dirty water, the connections being made from the side of the pipe instead of the top, in order to prevent accumulation of air pockets.

The orifice shown in Fig. 2 is segmented, having a narrow annular ring around the edge of the pipe, the dam or restricting portion being a segment immediately in front of the pressure connections. In the case of measuring steam the pressure-connection pipes are usually at the side so as to be free from accumulated air and also to form a reservoir for maintaining equal water level in the two connecting pipes. A radiator is supplied so that as soon as there is a displacement of water caused by the motion of the meter, steam is condensed to take its place and maintain equal water level in both pipes.



FLUE GAS ANALYSIS (PERCENT BY VOLUME)
CO

PERCENT AIR REQUIRED-100=% EXCESS AIR
STEAM FLOW MEAN FLOW TOGETHER WITH THESE CONDITIONS
LARGE COMBUSTION SPACE
MEDIUM COMBUSTION SPACE
SMALL COMBUSTION SPACE
TOTAL FLUE GAS LOSS
PERCENT HEAT LOST IN FLUE GASES
EXCESS AIR LOSS
UNBURNED GAS LOSS

FIG. 4.

The orifice, as well as the pitot and venturi tube, produces a differential pressure proportional to the square of the velocity of the flowing fluids. The extremely small differential at the lower rates of flow makes it difficult to secure the desired accuracy over the lower ranges. For instance, the differential pressure is only 1 per cent. of the maximum when the rate of flow is 10 per cent. of the capacity of the meter.

Fig. 3 shows a specially shaped bell which is sealed in mercury, and weighted on the outside of the mercury reservoir so as to be submerged to the point of greatest diameter in the position of zero flow. The higher pressure from the inlet side of the orifice is connected through the centre pipe to the interior of the bell, while the lower pressure comes into the meter casing. When metering steam or water, the entire casing and connecting pipes are filled with condensed steam.

A slight differential pressure produced by the lower rates of flow introduces a force over the entire area of the bell, pushing it upward. As the bell rises to the position shown in the diagram, the differential pressure corresponding to the change in mercury level, within and without the bell, pushes the bell upward until the emerged volume of tbe walls of the bell equals the volume of mercury displaced in the interior. The shape of the bell is so designed that the motion is directly proportional to the rate of flow.

Meters to Show Relation.—The third class of meters showing the relation between different factors has been developed for the purpose of giving the power-plant operator the maximum amount of condensed net results directly.

In the case of combustion, to know merely the steam flow and the percentage of CO_2 is not sufficient, because it is very seldom that the highest percentage of CO_2 which can be obtained is that which should be striven for. Fig. 4 shows a diagram of gas analysis running from about 180 per cent. excess air to a deficiency of some 25 per cent. which represents producer gas conditions. It will be noted that the percentage of CO_2 falls off rapidly after the point of theoretical air supply is passed. In the case of furnaces having limited combustion space, CO_2 and unburned gases may start to form with an air excess of 60 per cent. and a CO_2 content of 11 or 12 per cent. In this case the most economical condition of fuel bed would be one which would produce these results while giving neither more excess air nor much unburned gas. The average of the better modern practice is shown in this diagram as the one corresponding to medium combustion space where the excess air can be reduced to 40 per cent. above the theoretical before the unburned gas is formed to any appreciable extent. This corresponds to about 13 per cent. of CO_2. It is obvious from the diagram that the combustion should be maintained at this point.

Under these ideal operating conditions a definite amount of air is required to support combustion. We may, therefore, speak of the heat produced per pound of air. This heat is capable of generating a certain amount of steam. We may therefore compare the amount of steam produced with the amount of air used for combustion and obtain a very reliable indication of the efficiency of the combustion.

This has been accomplished by a meter which records the steam output from the boiler reading directly in percentage, and also records the rate of air flow through the boiler passes.

Other types of meters belonging to this class include the rate of stoker speed, as well as steam flow and air flow, the latter being adjustable according to the evaporation per pound of coal, so that stoker speed readings should be synchronous with the steam and air flow, as long as the coal is being burned at the proper rate to carry the load.

PAPER ON FIRE CLAY MORTAR

A very interesting paper has recently been prepared by Raymond M. Howe, M.A., on the subject of "The necessity for care in the preparation and use of fire clay mortar."

It is a well-known fact, states the author that various materials, when added to fire clay either decrease or increase its refractoriness. Often these materials are added in order to cause the fire clay to set in the cold and their depressing effect on the refractoriness of the mortar is not generally comprehended. The paper is really designed to show, 1—the effect of such additions; 2—the possibility of improving the quality of refractory mortars through the addition of finely ground bats to fire clay; and third, the desirability of using thin joints.

Various tables are shown, also illustrations of effects of treatment on the bricks. The Elk Fire Brick Co., Ltd., Hamilton, Ont., who called our attention to this paper, state that they have a

Some Points in Boiler and Furnace Design*

Determining Whether an Economizer Will Pay—Brickwork In Furnace Design—Effect of Radiant Heat—Percentage of Rating For Economical Operation—Difficulties Encountered From Slag—How to Reduce Clinker Trouble

By DR. D. S. JACOBUS

TO approach perfection from a thermal viewpoint, a boiler and superheater, including its economizer and air heater, if used, should absorb a maximum amount of heat with a minimum draft drop. There are commercial elements entering into the problem that limit the application of this principle, and so many variables that each case must be considered by itself in order to arrive at the best arrangement. A relatively large amount of boiler-heating surface, with large flow spaces for the gases, if properly insulated to prevent undue radiation, would more nearly meet the requirements of absorbing a maximum amount of heat from a given weight of fuel burned with a minimum draft drop than a smaller amount of surface, although the latter would in most cases be preferable from a commercial point of view. Adding an economizer will ordinarily add to the thermal efficiency; the same applies to an air heater, but here again, on considering the commercial side, it may be found that the character of the load and the class of operation and fuel conditions are such that it will not pay to install an economizer or an air heater.

Determining Whether an Economizer Will Pay

In determining whether it will pay to use economizers in a new plant, the problem should not be approached by comparing the efficiency of a boiler with that of the same boiler with an economizer added to it. The proper way is to compare the results to be expected from boilers best suited for the service without the addition of economizers to those to be expected for the best combination of boilers and economizers.

It will sometimes be found for exceptional load conditions that a larger boiler properly designed and baffled will give better commercial returns, all features considered, than a smaller boiler with an economizer—or, for that matter, for any boiler that can be selected with an economizer. In the case of an old plant the question of whether it will pay to add economizers to the boiler is a more simple one to answer than for a new plant, as the added efficiency due to the economizers may be readily computed on the basis of the known flue-gas temperatures, gas weights, etc.; but here again the load conditions must be taken into account, as well as the fact that there will be an increased cost of upkeep and added complication through the necessity of installing an induced-draft apparatus.

For peak load service it does not usually pay to install economizers on all boilers. A good arrangement may be secured for some classes of service by adding economizers to, say, one-third of the boilers, operating them at a more nearly uniform load than the rest and cutting in those that have no economizers during the peak-load periods.

Another case where it does not pay to apply economizers is where boilers are used for stand-by service. The cost of fuel is a governing factor, and because of the increase in fuel costs during the last few years we are approaching more closely to European practice in the number of boilers so fitted.

In designing a boiler for use without an economizer, additional efficiency may be secured by adding to its height. Increasing it from, say, 14 to 20 tubes high will result in a considerable increase in efficency without a corresponding increase in the draft loss, as much of the draft loss in boilers comes through the turns made by the gases in passing over the baffles.

Wrought-steel economizers are coming into use to a greater extent than formerly. We have found that, if the oxygen content of the feed water is reduced so that it does not exceed 1-5 c.c. per liter, the corrosion is reduced to a point where it will not give trouble.

To avoid exterior corrosion through the condensation of moisture from the flue gases, the temperature of the feed water to the economizers must be kept above a temperature of about 120 dg. F., and for most work we recommend 140 deg. F., as this allows for some leeway in case the water is fed intermittently. There is more difficulty through exterior corrosion in intermittent service than where the service is more or less continuous, as soot that collects on the outside of the economizer is likely to become moist where the economizers are down or are being started up, and the presence of moisture makes the soot from certain fuels highly corrosive.

It is becoming more general practice to use an individual economizer on each boiler and not to install connections for bypassing the bases around the economizer. A bypass connection as a rule allows some leakage of the hot gases and causes a continual loss of efficiency, and its omission is also advantageous in simplifying operation and lessening the chance of trouble with the economizers.

Brickwork in Furnace Design

For securing the highest efficiency the furnace temperature should be the maximum that can be maintained, and combustion should be completed within the furnace chamber. The furnace brickwork employed to-day will fail if saturated with heat at the full temperature that is available with many classes of fuel. In furnace design, therefore, some efficiency must be sacrificed in most cases in order to maintain the furnace brickwork and keep the cost of repairs within a reasonable figure. If it were possible to secure refractories for furnace construction that could be brought up to the full available temperature, the art of furnace design would be considerably changed, but as it stands to-day most of the thickness of the brick work must be cooled to a temperature below, say, 2,200 deg. F. in order that the bricks or tiles will carry the load imposed on them. To accomplish this a sufficient amount of the heat absorbed by the brickwork must be dissipated either through radiation or convection.

Where furnaces are operated under a suction that causes the cool air to be drawn inward through the brickwork, there is a cooling effect that serves to prevent overheating, whereas if they are operated under a pressure, there is a tendency for the hot gases to leak outward and overheat the brickwork. The difference between running with a slight suction of, say, 0.10-in. water column and a plus pressure within the furnace may make all the difference between successful operation and having a lot of trouble. If it were possible to operate with a plus pressure and maintain the brickwork irrespective of the temperature to which it would be raised, more economical results could be secured in most cases through the elevation of the furnace temperature. The exception would be where the elevation of temperature would interfere with the combustion; for example, with some kinds of coal too high a temperature might fuse the ash and clinker and cause the coal to mat down on the grate so as to greatly increase the air resistance through the fuel bed and reduce the available capacity. Again, if it were possible to bring the brickwork up to the full furnace temperature, arches could be used for certain purposes in furnace design where they can not at present.

Brickwork will fall by plastic deformation before it reaches the melting point.

*Abstract of a paper delivered before the Cleveland Engineering Society and local section American Society of Mechanical Engineers at Cleveland, and the Akron Section at Akron, Ohio, April 26 and 27, 1921.

The greater the load carried by the brick the more likely it is to fail. Fireclay brick of the best quality ordinarily obtainable begins to show plastic deformation under a load of 20 lb. per sq. in. at from 2,200 to 2,400 deg. F. Reduction to a load of 10 lb. per sq. in. will increase the permissible temperatures about 200 deg. F. As furnace temperatures considerably higher than this exist with certain grades of fuel and stoker practice, say, 2,700 to 3,000 deg. F. as a limit, it is apparent that the necessity of maintaining the brickwork below the temperature of the furnace is a vital one. First-class clay brick have a fusion point slightly above 3,100 deg. F., and yield through plastic deformation long before they fuse.

In ordinary furnace design the walls and arches are heated on one side only in order that the brickwork may be maintained at a lower temperature than that of the furnace. Arches will give trouble if heated on both sides which would not if subjected to the same amount of heat on one side only. This sometimes makes necessary the use of double arches, one directly above the other, with a small amount of air admitted between them for ventilating and cooling. A wall of a given thickness that would give good service as a battery wall might fail under the same fuel and combustion conditions if used as a supporting wall between two combustion arches, as the heat would not be conducted away from the wall to the extent that it would when used as a battery wall, and the reflected heat from the arches would also increase its temperature. Such a supporting wall should be used between combustion arches only in cases where a low grade of fuel is burned which does not result in high temperatures, or it should be ventilated.

To consume the combustible gases within the furnace chamber there should be a proper length of flame travel before the gases strike the tubes and a sufficient furnace volume. Furnace volume and length of flame travel are not, however, the only elements that must be considered in designing an efficient furnace, as there must be a mingling action within the furnace to cause any unconsumed combustible gases to reach the excess air.

Effect of Radiant Heat

The effect of the absorption of radiant heat on the boiler tubes should be considered in designing a furnace. With certain fuels such as blast-furnace gas, wet wood or bagasse, where the highest attainable temperature can be carried by the brickwork, it is best to absorb but little radiant heat in order to maintain a high furnace temperature and thereby increase the efficiency of combustion. With the stronger fuels it is necessary to absorb a considerable amount of the radiant heat in order to prevent the collapse of the brickwork or an undue amount of deterioration.

Few realize how great a proportion of the heat may be absorbed by a boiler as radiant heat. In underfeed-stoker practice, with the baffle arrangement ordinarily offered with Babcock & Wilcox boilers, the absorption of radiant heat with the boiler operated at its normal rated capacity is over 60 per cent. of the total heat absorption. Exposing more or less of the boiler surface to the direct radiant heat of the fire has a comparatively small influence on the efficiency, as any increase in the heat absorbed through direct radiation is counterbalanced to an extent by the diminution of the amount of heat absorbed through conduction. Ordinarily, the higher the furnace temperature the higher the efficiency. Higher furnace temperatures, however, lead to increased cost of brickwork maintenance, especially when the boilers are operated at high ratings, and for a strong fuel it usually pays to expose a considerable proportion of the heating surface of the boiler to the direct action of the radiant heat.

Percentage of Rating for Economical Operation

A question often arises as to what is the most economical capacity or rating at which a boiler should be run. This cannot be answered in a general way, as it depends on the load conditions as well as on the class and cost of the fuel. The economical rating is naturally influenced by the presence or absence of economizers and the service to which the boilers are put. Where there are short peak-load periods, the greatest commercial economy is usually secured by operating the boilers to as high a capacity as can be secured during these periods. Each case must be considered by itself and the fuel economy worked out for the actual conditions of service. The effect of the additonal cost of upkeep must naturally be considered.

The general practice in this country is to drive boilers at a higher rating than is done in European practice, and the stress of war conditions has undoubtedly led to a number of plants being run beyond the point of the best commercial efficiency. The fact remains, however, that boilers are being run at higher and higher capacities in our modern power plants, and the tendency seems to be upward rather than downward.

A furnace for operating at high capacities should be larger than for operating at lower capacities; a furnace to give economical results at high rating therefore involves special problems in caring for the expansion of the brickwork and especial care in the construction of buckstays for holding the brickwork in alignment. The general tendency in large furnace walls which are highly heated, is to bulge inward toward the fire, and unless some means are provided to prevent this, they may collapse.

In our present practice we use bonding tile which are held by cast iron bulb pieces attached to the buckstays in such a way that the wall can expand in any direction in a generally vertical plane, whereas it is prevented from either bulging inward or outward. Another means that may be employed to prevent the walls bulging inward toward the fire is to build them with a camber having a vertical axis, that is, curved slightly, with the concave side next the furnace.

Difficulties Encountered From Slag

In operating at higher ratings, difficulties are encountered with some grades of fuel through slag adhering to the boiler tubes and restricting or closing up the passage-ways for the flow of the gases. The difficulty through slag can be reduced by providing a relatively large area for the flow of the gases on entering the spaces between the tubes and by furnishing access doors through which the slag can be detached from the tube. An air lance, which is used both for cooling the slag and as a rod for striking it to remove any portion that may adhere to the tubes, forms an efficient tool for use in connection with the access doors.

The difficulty through slag is essentially a stoker-operating difficulty. Carrying a thick fire may result in but little slagging action, whereas this may cause trouble with the stoker itself through clinker. Thinner fires may remedy the clinker difficulties but result in a greater amount of slag being deposited on the boiler tubes. With certain grades of coal there will be some accumulation of slag on the boiler tubes with the stokers most carefully operated, and it is advantageous in such cases to provide access doors for removing the slag. Steam-jet blowers serve to reduce the amount of slag which will collect on the tubes, but are not a complete remedy so that it is often well to provide access doors.

How to Reduce Clinker Trouble

Trouble from clinker at the sides and front walls of the furnace where underfeed stokers are used is often reduced by admitting air through a number of openings in the walls at the sides of the fuel bed. The air flows in a layer against the inner face of the wall and prevents the clinker adhering to them. It also serves to partly cool the wall and reduce its erosion.

A stoker-operating difficulty that arises in some cases is the formation of a clinker which will cause the air admitted under a blast pressure to produce a jet or torch-like action that will result in fusing the brick so as to melt out or erode away a part of the wall. The stoker tuyeres may also cause jets of air to be projected against the wall so as to erode away certain parts of it.

It can readily be seen that furnace design and boiler design must be coordinated in order to secure the best results. It is impossible to separate boiler efficiency from the efficiency of the stoker and furnace. Many have worked

The Calculation of Boiler Performance

Horse Power Rating of Boilers—The Standard Definition—The Calculation by Reference to the Equivalent Evaporation—Chart For Quick Determination of the Factor of Evaporation

By W. B. CAMPBELL

By W. B. CAMPBELL

THE object of a boiler is of course to make steam, and on the face of it the most natural gauge of how much work it has done is the amount of steam it has produced, or, what is the same thing, the weight of the water it has turned into steam. But this is only the roughest kind of an approximation as to the working capacity of the boiler, because the pressure at which steam is produced makes a big difference. High-pressure steam is worth more in the engine than low-pressure steam, and is harder to make, and the additional service should properly be credited to the boiler. In fact, the only fair basis on which to state boiler performance is heat transferred to water. Heat is potential work, and the work to be had from steam is a function of the amount of heat in it, so that the heat content indicates the value of steam for power purposes. The production of steam is a problem of forcing heat through boiler tubes at a desired rate, so that steam-making can be judged by the heat transferred, whether to a small quantity of steam at high pressure, or a larger quantity at low pressure.

While the heat transfer could logically be expressed in B.t.u. an hour, the practical unit is the boiler h.p. B.t.u. are used only for figuring. No one has even seen one; and while a boiler h.p. is equally imaginary, it is a convenient idea, and has been used so long that 50 or 100 or 1,000 boiler h.p. suggests to the engineer a certain relative size of equipment, and indicates the ability to give a certain amount of service.

All horse-power ratings are purely arbitrary. A horse-power as a rate of doing work represents more than any ordinary horse could possibly do, for the reason that when Watt first started to sell his engines on horse-power basis, he purposely under-estimated their possibilities, which were greater than he could make people think they were. They were "too good to be true." When the engine h.p. was later defined on a scientific basis, it was therefore given the rather high value of 550 foot-pounds a second, or 1,980,000 foot-pounds an hour.

In a similar way the boiler h.p., now defined on an arbitrary basis, was intended to represent the production of steam at a rate which would serve to produce an engine h.p. At the time of the Centennial Exposition in Philadelphia, in 1876, the Committee of Judges established as a unit that a boiler h.p. should be the evaporation of 30 pounds of water an hour, receiving it as feed-water at 100 degrees and delivering it as steam at 70 pounds gauge pressure. Steam at 70 pounds contains 1,108.1 more B.t.u. a pound than does water at 100 degrees, so that the making of 30 pounds of steam an hour under such conditions represents the transfer of $30 \times 1{,}108.1 = 33{,}243$ B.t.u. an hour.

Subsequent to this the method was adopted of figuring on an "equivalent-evaporation" basis. The greater part of the work of producing steam is in supplying the "latent heat of vaporization," the heat which turns water into steam, changes its state without affecting its temperature, and is therefore considered as latent or hidden. The heat required to raise water from the feed temperature to boiler temperature varies, the latent heat required to evaporate it varies with the boiler temperature and pressure, and if super-heated additional heat is transferred. All of these heats can be added and reduced to the equivalent amount of water which they would evaporate from and at 212 degrees. It requires exactly 970.4 B.t.u. to change one pound of water at 212 degrees to steam at 212 degrees, and we therefore reduce by dividing the heat transferred by 970.4. The modern definition of a boiler h.p. by the American Society of Mechanical Engineers is the heat-transfer rate equivalent to the evaporation of 34.5 pounds of water an hour from and at 212 degrees. $34.5 \times 970.4 = 33{,}479$ B.t.u. an hour. This is only one-half of 1 per cent. more than the B.t.u. in the old Centennial definition, and the 34.5 pounds definition gives an easily calculated and well-recognized unit. It is universally used, and boiler performances are calculated on this basis. The actual weight of water evaporated is converted to the "equivalent evaporation" by the use of a factor of evaporation. A factor of evaporation of 1.15 means that for every pound of water actually evaporated, 1.15 pounds must be considered as having been evaporated—that is, the actual evaporation must be multiplied by 1.15. This equivalent evaporation is the only basis on which different boilers can be compared, or by which tests of the same boiler at different times, with different fuels, different baffling, different firing rules, different feed-water temperatures and gauge pressures, different rates of driving, etc., can be compared. The formulae for factor of evaporation are given below, although the results are all embodied in the chart:

$$F = \frac{(h + L + s\,S) - f}{970.4};$$

where

F = factor of evaporation;
h = heat of the liquid in saturated steam at boiler pressure, expressed in B.t.u. above 32 degrees a pound, taken from steam table;
L = latent heat of vaporization at boiler pressure, B.t.u. a pound;
S = degrees of superheat, or the excess of the steam temperature over what it would be for saturated steam at same pressure;
s = average specific heat of superheated steam (about 0.5 B.t.u. a pound a degree of superheat);
f = heat of the feed-water, B.t.u. above 32 degrees a pound. This can be taken from steam table, but is approximately equal to the feed temperature, minus 32;
970.4 = B.t.u. required to evaporate one pound from and at 212 degrees F.

The more exact value of s is

$$0.43 + 1{,}476{,}000 \frac{\text{gauge pressure}}{(\text{temp.} + 460)}.$$

Using this formula for saturated steam at 75 pounds gauge evaporated from water at 180 degrees—

$$F = \frac{290 + 894 + 0 - (180 - 32)}{970} = 1.06.$$

Turning to the chart, we start at the 75-pound gauge pressure point at the bottom of the right-hand half, run up vertically to the horizontal "dry saturated" line; the intersection lies between the fourth and fifth curved lines. Follow at the proper distance between these lines to the "north-west" till we strike the 180-degree feed-line, and we find the factor of evaporation to be 1.06.

If we have steam at 170-pound gauge and 75 degrees superheat from feed-water at 190 degrees, we follow the 170-pound line up to the 75-degree superheat line (as shown dotted on the chart), then follow the curves in the direction shown dotted to the 190-degree feed line, and find the factor of evaporation to be 1.095.

The line below the gauge pressures gives the temperatures for saturated steam at each pressure. These relations are established; steam in contact with water is necessarily at a temperature corresponding to its pressure. However, in a superheater, steam will be at the same pressure as the rest of the boiler, but takes up additional heat which heated steam faster than it has a chance raises the temperature of the super-

to equalize itself. The excess temperature over that belonging to the pressure is the amount of "superheat"; if not stated directly, it is obtained by subtracting the saturation temperature from the final or actual temperature.

The quality of steam is expressed as a percentage of the whole weight which is really steam, and not small drops of water carried over. If the quality is over 96 per cent. it can be estimated by expanding the steam to atmospheric pressure through a throttling calorimeter, and noting the resulting temperature.

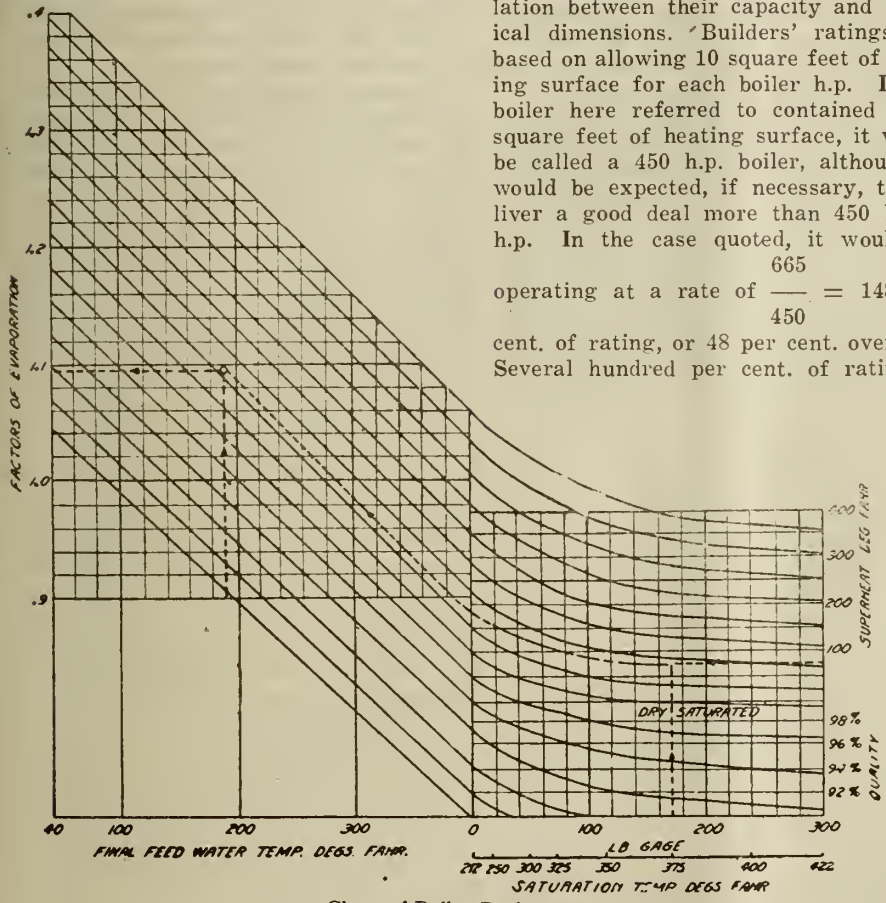

Chart of Boiler Performance.

$$Q = \frac{1{,}150.5 - h + 0.46\,(t - 212)}{L};$$

where

Q = quality of steam;
h = heat of liquid at boiler pressure, from steam table;
t = temperature after expansion;
L = latent heat of steam at boiler pressure, from steam table.

If the steam is "wet" in this sense, the equivalent evaporation must be corrected accordingly, as each drop of water carried over while it is at boiler temperature has not taken up any heat of vaporization. This is allowed for in the lower part of the right-hand chart. For the evaporation of 200-degree feed-water to steam at 200-pound gauge pressure, 98 per cent. quality, follow the 200-pound line to the horizontal 98 per cent., then the curve to the left to the 200-degree line, and factor of evaporation equals 1.04.

As stated above, the equivalent evaporation is the actual multiplied by the factor. For instance, if 500,000 pounds of water is actually fed to and evaporated by a boiler in 24 hours and the factor of evaporation is 1.1, the equivalent evaporation is 550,000 pounds in 24 hours.

$$\text{Boiler h.p.} = \frac{550{,}000}{34.5 \times 24} = .665 \text{ h.p.},$$

and this is the average boiler h.p. actually developed during the day. Boilers are driven at so many different rates that it is hard to establish an exact relation between their capacity and physical dimensions. Builders' ratings are based on allowing 10 square feet of heating surface for each boiler h.p. If the boiler here referred to contained 4,500 square feet of heating surface, it would be called a 450 h.p. boiler, although it would be expected, if necessary, to deliver a good deal more than 450 boiler h.p. In the case quoted, it would be operating at a rate of $\frac{665}{450} = 148$ per cent. of rating, or 48 per cent. overload. Several hundred per cent. of rating is delivered by large units during peak-load periods, although with some loss in efficiency.

This equivalent evaporation can also be used as a gauge of the performance of the boiler and furnace with respect to the fuel used. For the figures quoted, if the evaporation was secured by burning 70,000 pounds of coal containing 2 per cent. moisture and 8 per cent. ash, the equivalent evaporation a pound of coal would be $\frac{550{,}000}{70{,}000} = 7.85$, the equivalent evaporation a pound of dry coal would be $\frac{550{,}000}{70{,}000 \times 0.98} = 8.01$, and that for a pound of combustible would be $\frac{550{,}000}{70{,}000 \times 90} = 8.71$. If the refuse from the furnace was 11 per cent., the equivalent evaporation per pound of combustible actually burned would be

$$\frac{550{,}000}{70{,}000 \times 0.87} = 9.02.$$

Efficiency (combined) of boiler, furnace and grate is figured by comparing the heat transferred to steam with the potential heat in the fuel. The latter is generally determined in a calorimeter by burning a small sample of the fuel in a closed bomb, under such conditions that the full heat is developed, and is measured by allowing it to heat a known quantity of water surrounding the bomb, a B.t.u. being defined as the amount of heat required to heat a pound of water 1 degree F. The heat value of coal runs from 13,000 to 16,000 B.t.u. a pound.

Each pound of equivalent evaporation represents 970.4 B.t.u. transferred, therefore the efficiency equals

$$\frac{\text{Equiv. evap.} \times 970.4}{\text{Weight of coal} \times \text{heat value}}.$$

In the example, if the coal contained 13,800 B.t.u. a pound of dry coal, the efficiency would be

$$\frac{550{,}000 \times 970.4}{70{,}000 \times 0.98 \times 13{,}800} = 56.4\%.$$

This means that 56 per cent. of the potential heat in the coal has been successfully transferred to steam. A heat balance can be made to cover the various source of loss, such as the evaporation of moisture in the coal; heat carried off in steam made when the hydrogen in the coal burns; heat lost in flue gases, depending on their temperature and the amount of excess air in them, indicated by the CO_2 analysis; any unconsumed CO in the gas, unburned coal in the refuse, moisture in the air, radiation, etc.—"Southern Engineer."

POINTS IN BOILER DESIGN

(Continued from page 27.)

on this problem, and the ground has probably been gone over more thoroughly than any other feature of boiler-testing codes. The result has always been in reaching the conclusion that it is impossible to separate the furnace and stoking efficiency from the combined efficiency of the boiler, stoker and furnace in such a way that the result may not be misleading.

HINTS OF VALUE

Shortly after a fire in a certain plant in England the following hints were given: Don't store oily cotton waste in a warm place at all, and don't store it where firing will cause danger anywhere. Under favorable conditions oily waste, as well as some other things, will oxidize rapidly, and in the presence of air will ignite through the heat engendered; and this should be thoroughly knocked into the heads of people handling the stuff in workshops, as it is quite easy to have a fire from some "unknown cause," or of which the "origin unknown" report is given by the fire brigade.

A Course of Instruction for the Graded Certificate

In This Article Some Illustrations Are Given of Cards From a Slide Valve Engine and Their General Appearance Explained. —These Are the Most Simple Examples of Indicator Cards

By T. H. FENNER

THERE is probably no more interesting operation to the average engineer than taking indicator cards to observe the internal working of his engine. A proper understanding of the diagram drawn by the indicator is a big help to the efficient working of the plant. We have to consider first of all the indicator card in its relation to valve setting. Let us take first of all a slide valve engine, and assume that the valve and eccentric have been set approximately, and we are now about to make final adjustments by means of the card.

After adjusting the cord so that we are sure the drum of the indicator will not come up against its stops at either end of the stroke, and allowing the steam to act on the piston from each end of the cylinder for a few strokes to get the indicator pipes clear of moisture and to make sure the indicator is working freely, a card is placed upon the drum and we are ready to go ahead. A card is taken from each end of the cylinder on the same paper, so that we can have an indication of the relation of the two ends to each other. The cards obtained from the engine will depend a great deal on whether the governing is by throttle or by automatic cut-off. We will first consider the throttling governor, and the engine running light. Assuming that the initial pressure is 100 pounds and we are using an 80-pound spring, we will not expect to get a card much more than an inch high at its highest point. The throttling governor will cause a considerable wire drawing of the steam, so that the pressure in the steam chest will be low, and the steam line will drop rapidly, the point of cut off of course remaining the same whatever the load condition may be. The card we will get would be somewhat similar to Fig. 1.

The steam line is lower than the height corresponding to the initial pressure due to the wire drawing as already explained. From the beginning of the stroke the steam line will drop rapidly in a practically straight line until the cut-off point is reached, and the pressure will very likely drop below its atmospheric line before the exhaust opens. There will be but little compression, owing to the steam remaining in the cylinder being at atmospheric pressure.

These cards will be useful only in a general way to show how the distribution is divided on each side of the piston. If there is any serious discrepancy between the points of cut-off and compression on head or crank end it will be shown, but if the cards appear fairly even we must get some load on the engine to give a clearer indication. With the steam very much throttled it becomes a difficult matter to determine just where the cut-off point is, and also the compression but with the engine working at about its full load we can see clearly what is taking place.

The card shown in Fig. 2 is a good example of a slide valve engine cutting off about half stroke, and with the valve set at practically the best position. It will be noticed that the cut-off takes place at about the same point in the stroke at both ends of the cylinder, compression takes place similarly, and cut-off is even. The work done at each end of the cylinder will be practically the same, allowing for the slight loss in

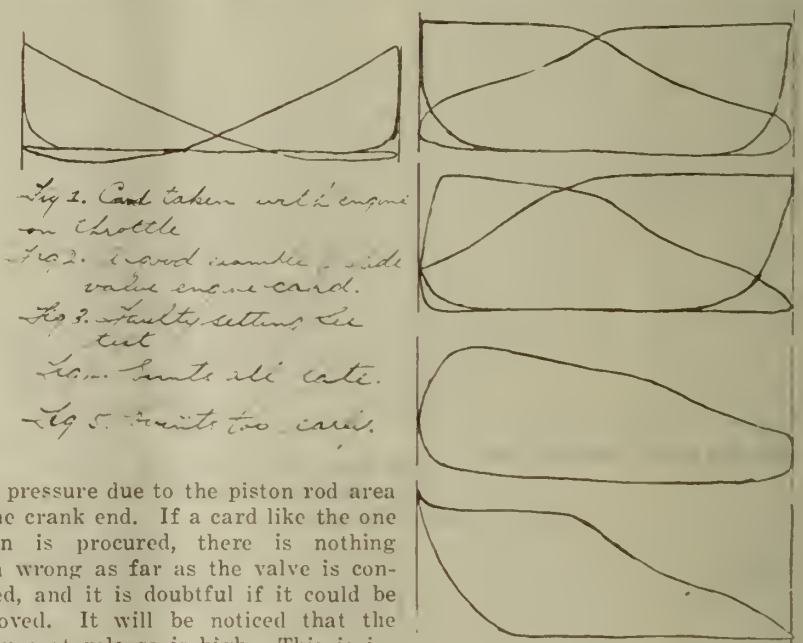

Fig 1. Card taken with engine on throttle
Fig 2. Good example of slide valve engine card.
Fig 3. Faulty setting of cut
Fig 4. Suits all cases.
Fig 5. Suits two cases.

total pressure due to the piston rod area on the crank end. If a card like the one shown is procured, there is nothing much wrong as far as the valve is concerned, and it is doubtful if it could be improved. It will be noticed that the pressure at release is high. This is inevitable in plain slide valve engine working with an unvariable cut-off. The practically straight steam line shows that the ports are ample in size to supply the steam up to the point of cut-off, and the straight exhaust line shows that the steam is released speedily and without any accumulation of back pressure.

The next figure shows a card indicating faulty valve setting, and we must look into this carefully before deciding what is the matter and what is the remedy. Taking the left hand card first, we note that the admission line slopes inward from the end of the card, and that the piston has started on its stroke some little time before the steam has attained its maximum pressure. Following the steam line along, we note that the pressure does not keep up as in the former figure and that the cut-off takes place earlier than in the first card. The expansion curve is shorter owing to the fact that the valve opens to release earlier, while on the return stroke, the valve does not close to exhaust till nearly the end of the stroke, making the compression curve small.

Let us now consider the card from the other end of the cylinder. Here the conditions shown are practically the opposite. The valve opens to admission earlier, thus giving a line sloping outwards to the end of the card, and resulting in the pressure being reached before the piston is at the end of its stroke. Following along we find that the cut-off takes place later, and the expansion curve is continued further before release takes place. Tracing along the exhaust line we find that the compression curve starts sooner, and is larger than on the opposite side. What do we deduce from all these points? We find that on the left-hand card we have some events early and others late, while on the right-hand card we have the events occurring in an exactly opposite manner. That is, where admission is early in one case, it is late in the other; where cut-off is early on one end it is late at the other. What is the fault and what is the remedy with this valve setting? Taking the left-hand card first, and neglecting for the moment whether that is the head or crank end card, we see that admission is late and cut-off early, while release is early and compression late. From this card we judge that the valve should be moved

on the spindle. Let us assume that the left-hand card is taken from the crank end, then the valve should be moved on the spindle away from the crank. However, we must consider what effect this will have on the card from the other end. In this card we have admission early, cut-off late, release late and compression early. The valve being moved on the spindle towards the head end will also correct these faults. It might be that merely moving the valve on the spindle would not be enough, and in that case the eccentric would have to be moved ahead a small amount and the valve adjusted on the spindle to make each end correct.

Let us consider a moment the case if, still considering the same pair of diagrams, the left-hand card had been from the head end and the right-hand had been the crank end card. In that case in order to correct the head end we should have had to move the valve towards the crank end. This, however, would have tended to neutralize the early lead and late cut-off on the crank end which is what we want to keep. The remedy then would be to advance the eccentric, to make the head end correct, and to move the valve back on its spindle to make the crank end correct.

Where every event is early as we have seen in previous articles the remedy is to turn the eccentric back. Where everything is late the remedy is to turn the eccentric ahead. If the reader will turn back at this stage to the Zeuner valve diagrams that were discussed in the earlier lessons, he will be able to derive considerable help therefrom. In studying a card remember always this rule. If two events are late and two early the valve must be moved on the spindle to correct those faults. If correcting the fault this way is going to make the other end of the cylinder wrong, then the remedy is to move the eccentric a little way to make everything early or late, and then make the adjustment on the valve spindle. If all events are either early or late move the eccentric. This is a general rule which covers all cases, but there are many modifications which become necessary according to conditions. With a simple slide valve engine there are only the two operations possible but with four-valve engines there are, of course, a number of other adjustments to be made.

The cards shown here are fairly typical cards from a slide valve engine without any complications, and should be quite simple for the student to follow. As we go into this subject we shall have much more complicated illustrations, but we just start at the beginning. It is so easy to draw wrong impressions from the reading of a card that we want to make it very clear in these articles just what each sign means.

When studying a card always approach it from the angle of the perfect card and note where the events differ from that. You won't have a perfect card always with you, but you should retain a very good idea of what it looks like in your mind. Another useful thing is to apply the diagram shown earlier and which we reproduce again here showing the direction of the valve and direction of the piston throughout the stroke. This applies not only to slide valve engines, but to any other kind of engines, and is a most useful thing. Get familiar with the main facts of the card's message, and then you will soon be able to recognize faults and their remedies as soon almost as you look at the card.

AN UNUSUAL FATALITY

In the course of an inquiry into certain types of water tube boilers used in the British navy during the war, and defects that occurred therein, a most unusual fatality was mentioned.

During the hydraulic testing of one of these boilers, a failure of the sheet occurred, in such a way that it split open about three feet along the length, and a sheet of water was projected through the crack. This water was, of course, at very high pressure, probably in the neighborhood of 700 or 800 pounds per square inch, and possibly more. One of the men engaged in the test was stationed at the place where the fracture occurred, to watch the necks of the tubes for leaks, and the sheet of water issuing with such force cut him in two. This is one of the strangest accidents we have ever heard of in a long experience. It shows that there can be danger where it is least expected. As everyone knows the reason that water is used for testing vessels under pressure is because there is no danger of explosion if anything gives way. Water being incompressible, that is practically so, a sudden rupture would merely result in a drop of pressure. However, in a case such as is mentioned above, the opening made in the plate was of very small area, and the man being close up to it received the full force of the jet issuing from it, and probably the pump was still working when the accident occurred.

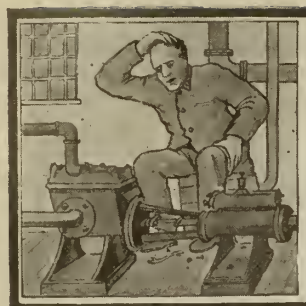
We remember an incident that showed very vividly the power of a jet of water at high pressure. The occasion was that of testing some hydraulic valve boxes to a pressure of 2,000 pounds per square inch. The nipple to which the pressure gauge was connected failed in some way, and the gauge parted company with it. A jet of water issuing from the opening carried the gauge up and up till it reached the roof of the building, and a skylight being directly in its path went through this and out into the street beyond. That roof was a good sixty feet, the building being the erecting shop of a large engineering firm. That was in no sense an explosion, but merely a jet of water at high pressure which gave the gauge the initial velocity which carried it on its upward path. Thinking of this makes it more easy to understand the knife-like force that the sheet of water issuing from the boiler would have to enable it to cut a man in two.

The U. S. Bureau of Standards has made an interesting investigation on the influence of abrasion on the hardness of the various types of steels. "In all cases, except the high-carbon austenitic steel," says the report, "no pronounced effect of abrasion upon the steels used in these experiments was observed. In all cases the hardness of plain carbon steel containing 0.85 per cent. shows the greatest increase in hardness. The alloy steels generally show a smaller increase in hardness of abraded surface than plain carbon steels, and in some cases they show a decrease of surface hardness. High-carbon austenitic steel shows a marked decrease of Brinell and scleroscopic hardness. This process of abrasion viewed in the light of Beilby's theory may be considered as resulting in the reduction of amorphous matter at the expense of crystalline matter, which affects the hardness of the abraded surface of the metal, but probably not the general character of its structure.

Newcastle, in Northern Natal, situated on the main line about half way between Durban and Johannesburg, and long noted for its coal fields, is likely soon to be also an important ironworks center, states the London Ironmonger. The Newcastle Iron and Steel Works, of which J. K. Eaton is the managing director, are nearly completed, and it is expected that the production of pig iron will commence in the early summer. Owing to the scarcity of cast iron at a reasonable figure. It is said that the Newcastle company will be able to sell its products at about the present price of cast iron scrap, which is what the South African foundries greatly need.

RAIL JOINT WELDING

The welding of rail joints where the rails are laid in paved streets, or when the main highways cross the tracks, is becoming popular with the steam railroads in the United States. The Baltimore & Ohio is said to have been the first railroad to adopt the welding of rail joints, nearly one hundred joints being welded on Pratt street, Baltimore, in 1917, the rails in this instance weighing 141 lbs. to the yard. The success attending the innovation has led to its extensive use. In the case of highway crossings the general practice is to weld three rails together in the nearest shop and quickly install them without interfering with the traffic. Once installed, they may be said to require no further attention, as no joint repairs are necessary, many having been in service for a lengthened period without showing signs of weakness or failure.



OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

SURFACE OR JET CONDENSER

Question:—What is the advantage of a surface over a jet condenser, or is there any particular advantage? Which one will give the highest vacuum? What would determine the choice?

Answer:—Surface and jet condensers are used in different places according to the conditions as to feed water, circulating water, etc. With a jet condenser the exhaust steam mixes with the condensing water, and if this water is not fit for boiler feed, both exhaust steam and condensing water are lost. The jet condenser is a very simple affair, the circulating pump and condenser being self-contained. If it is intended to use the exhaust steam to feed the boiler it is better to use a surface condenser. In this case besides the circulating pump an air pump must be used, to draw the condensation from the condenser and deliver it to the hotwell, where the feed pumps return it to the boiler. As a rule in stationary practice, where feed water is cheap, no attempt is made to return the engine exhaust to the boiler. In some cases, the circulating water and exhaust steam from the jet condenser are returned to the hotwell. This is the exception, however, and usually in stationary practice the amount of oil in the exhaust precludes the use of the condensation in the boiler. The surface condenser is mostly restricted to marine work, where the exhaust must be used for feed water, and where the consumption of cylinder oil is cut down to a minimum. In large central stations using turbines surface condensers are sometimes fitted. Generally speaking the surface condenser with air pump will give a better vacuum than the simple jet condenser, but a barometric jet condenser with dry air pump will give very high vacuum if everything is kept tight.

HOW LONG SHOULD BOILER BE RUN?

Question:—What is the longest time that it is safe to run a boiler without washing out, and can a horizontal boiler be run longer than a water tube?

Answer:—The length of time between washing out a boiler will depend on the quality of the feed water, and the rate the boiler is worked. If the boiler is run at normal rating, it will require cleaning less often with the same quality of feed water as if it was run at 150 or 200 per cent. over rating. With a horizontal return tube boiler and ordinary good water, the boiler should be opened up once a month under ordinary circumstances. That is long enough to run this type of boiler, and of course if conditions are hard more frequent opening up will be required. With a water tube boiler it is different, and they can be run anywhere from two to six months with perfect safety. In the horizontal type of water tube boiler the lower rows of tubes can be examined from time to time and their condition is a good guide to the rest, for the lower rows get the most heat, and therefore will have the heaviest deposit. In general, would say that the length of time a boiler can be run depends entirely on local conditions but the above limits are reasonable.

SAFETY VALVE ADJUSTING RING

Question.—What is the adjusting ring on a safety valve, and how does it act?

Answer.—When a safety valve lifts it is under greater compression than that due to the initial compression of the spring, due to the extra compression it gives by lifting from its seat. To overcome this a lip is formed on the valve, so that when it opens the arc of the valve is greater than when it is closed. This extra area gives a greater force to the lifting effect of the steam. The adjusting ring is made to screw up or down to approach closer to this lip or further away from it. When it is close to the lip the steam has not such a free discharge, and it will take a greater drop in pressure before the spring can overcome the upward force on the valve. When the ring is far away from the valve the steam has a freer discharge and does not act so directly on the lip of the valve, therefore the valve will close with a much less drop in pressure, giving the pop action from which the valve gets its name. The ring can be adjusted while the valve is discharging by means of a rack, which can be reached through a small hole in the body of the valve.

DYNAMO OR MOTOR

Question.—What is the difference between a dynamo and a motor?

Answer.—The difference between a motor or dynamo is this: A dynamo is a machine for converting mechanical energy into electrical energy, while a motor is a machine for converting electrical energy into mechanical. Therefore if an electrical machine is driven by a prime mover it will deliver current on to a circuit, that is, it will be a generator. If you take the same machine and connect it up to a source of electrical power and supply it with current it will in turn drive any other machine by means of a belt or being directly coupled.

FINDING THE SIZE OF PUMP

Question.—How would I find the size of pump required for a boiler evaporating so many pounds of water per hour?

Answer.—The way to find the size of pump required is as follows: Supposing that each pound of coal evaporates 8 pounds of water, and the coal consumption is 500 pounds per hour then you will have to feed 4,000 lbs. of water per hour. This is equivalent to 4,000 divided by 62.5 or 64 cubic feet of water per hour. Allowing that you wish the pump to run about 24 strokes per minute, or 12 double strokes, which is the same thing, the pump will move if 100 per cent. efficient 64 divided by 60x24 cubic feet per stroke. As you must allow for slip, and it is best to be on the safe side, the pump should be considered only 80 per cent. efficient, and should therefore be large enough to move $\frac{64 \times 120}{60 \times 24 \times 100}$ cubic feet per stroke. Multiply this to reduce it to cubic inches by 1728, the result being 92.16 cubic inches, or say 93 cubic inches per stroke. In order to have a long stroke we will assume twelve inches as the stroke, and the diameter will then be found by dividing 93 by $12 \times .7854$ and extract the square root or $\frac{93}{12 \times .7854}$ which gives a diameter of a little over three inches. This is not a very well proportioned pump, so we will try a shorter stroke and larger piston. Suppose we take the stroke at eight inches then we shall have $\frac{93}{8 \times 7854} = 3.84$ ins. dia. It would be well to make the pump 4 ins. dia. by 8 ins. stroke and then it could be run slowly. This proportion gives practically 100 cubic inches per stroke and with 24 strokes per minute you would have 2,400 cub. ins. per minute or 1.38 cubic feet. This multiplied by 60 gives 82.8 or say 83 cubic feet per hour. Allowing 20 per cent. for slip you have $\frac{83 \times 100}{120}$ 70 cubic feet per minute, which is more than we require, but gives a safe margin.

Programme of the C. A. S. E. Convention.

The convention to be held at Ottawa on the 28th, 29th and 30th of June promises to be the most successful in recent years. Everybody concerned has been putting forth strenuous efforts to secure a good programme, and a good collection of exhibits, and from all accounts have succeeded.

The exhibition will be held in St. Patrick's Hall, Laurier Avenue, Ottawa, and a very comprehensive round of entertainment for the delegates and visitors has been arranged by the entertainment committee.

The following official programme will give an idea of what awaits those attending:

Tuesday

10 a.m.—Meeting Grand Lodge C. A. S. E., R. C. Leach, president, in the chair.

11—Opening ceremonies, C. Berry, president Ottawa Lodge, in the chair. Speeches by civic representatives and visitors.

2 p.m.—Business session.

4 p.m.—Adjourn to Exhibition Hall to examine exhibits.

7.30—Boat trip, as guests of the Ottawa lodge.

Wednesday

9 a.m.—Business session.

1.30—Drive around city, leaving Convention Hall at 1.30.

2.30—Games at Exhibition Park.

8 p.m.—Entertainment at Convention Hall.

10—Drawing for prizes.

Wednesday Evening, E. F. Hetherington, Galt, chairman. Talent includes Jack Armour, E. B. Curzon, Bob Jones, Howard Fletcher, etc.

Thursday

9 a.m.—Business session.

Election of officers.

Selecting place of next annual convention.

10—Annual meeting Exhibitors Association.

2 p.m.—Open meeting C.A.S.E. for installation of officers.

Officers of Exhibitors Association

Honorary President: C. Berry, 40 Willows St., Ottawa.

Past President: J. S. Mock, 1305 Bank of Hamilton Bldg., Toronto.

President: C. B. Turner, 894 Bathurst St., Toronto.

1st Vice-President:Grant E. Cole, 1002 Dundas St. West, Toronto.

2nd Vice-President: E. B. Curzon, 120 Prince St., Montreal.

Secretary: Gordon C. Keith, 51 Wellington St. W., Toronto.

Assistant Secretary: Bob Jones, France Packing Co., Tacony, Pa.

Treasurer: Lloyd M. Archibald, 93 Niagara St., Toronto.

Exhibition Committee: A. Betton, (chairman.)

Entertainment Committee: E. F. Hetherington (chairman); W. H. Auger, W. J. Worthington, L. M. Archibald, H. G. Fletcher, George M. Wilkinson, G. C. Keith.

Reception Committee: John Thompson (Chairman.)

Next Exhibition will be held at Ottawa, June 28, 29 and 30, 1921.

J. S. MOCK, Past President

E. B. CURZON, 2nd Vice-President

C. B. TURNER President

GRANT E. COLE 1st Vice-President

G. C. KEITH Secretary

L. M. ARCHIBALD Treasurer

E. F. HETHERINGTON Chairman Entertainment Committee

J. THOMPSON Chairman Reception Committee

A. BETTON Chairman Exhibit Committee

BOB JONES Assistant Secretary

OFFICERS OF EXHIBITORS ASSOCIATION

The annual exhibition of power plant equipment and supplies will be held in St. Patrick's Hall, 77-79 Laurier Ave. West, Ottawa, June 28, 29 and 30, 1921.

The Thirty-Third Convention

AT the end of June the Canadian Association of Stationary Engineers will hold their thirty-third convention, the scene chosen for this year being Ottawa. Ottawa is a very pleasant city to hold a convention in, and there is no lack of interesting features from a power plant engineer's point of view. The close proximity of Hull will no doubt be far from a drawback, and furthermore there are some fine examples of industrial progress on that side of the Ottawa River. The immense plants of Booth's and Eddy's are well worth a visit, and these are not the only ones. On the Ottawa side perhaps the principal attraction from an engineering standpoint will be the new heating plant of the Parliament Buildings, while those who are interested in refrigeration will no doubt find a chance to visit some of the breweries which have their location in Ottawa. Apart from any question of engineering sight-seeing, Ottawa abounds in picturesque drives and trolley rides. The drive round the Rideau and out to the experimental farm will be found well worth while, and for those who want to go sailing or bathing Britannia Beach holds forth lots of attraction. The delegates ought to be able to put in three very good days.

The foregoing should be guarantee that there need be no dull times for the delegates in their off moments. There is another thing that we would respectfully draw to the attention of those attending the convention, and that is the exhibit supplied by the various manufacturers and agents of power house accessories and appliances. These firms go to considerable trouble and expense each year to make this exhibit, and they also do their share to make the convention a success from a social point of view. They are glad to do so, and want to see every convention a great success, each one better than the one before. In return all the exhibitors ask is that the delegates and visitors to the convention will spare a little time to visit the various exhibits, and ask for any information they may wish to acquire. It is well recognized that the delegates particularly are kept pretty busy, but at some period of the three days a spare hour can be found to look over the latest productions of the manufacturing engineers which will be found in the exhibition hall. The dates for the convention will be the 27th, 28th and 29th June and in the next issue of Power House we will publish the programme and all the information that will be of use to visitors.

A Remarkable Accident

THERE has been brought to public notice through the medium of an enquiry into the behaviour of water tube boilers of a special type during the war, a most unusual fatality.

Many ships of the navy were fitted with the Yarrow type of water tube boiler, and to those of our readers who are not familiar with this design, we may say that it consists of three drums, one on top and two below arranged in the form of a triangle. The lower drums are water drums, and the upper one a water and steam drum, and the upper and lower drums are connected together by small diameter tubes. In order to have these tubes straight the drums were flattened on the side where the tubes entered, and due to this construction, some failures occurred. One vessel's boiler blew up while she was in harbour, and there were several bad accidents on other war vessels accompanied by fatalities.

The case in question, however, is remarkable in that it occurred while the vessel was in harbour, and the boiler was being tested hydraulically. The pressure used is not given in the report, but as these boilers carry a working pressure very often of 300 lbs. per square inch it is safe to assume that the hydrostatic pressure would be at least 600 lbs. to the square inch. One of the men engaged in the test was stationed at the lower water drum, and was looking at the necks of the tube to see if there was any leak from them. In order to do this he would have to stand close up to the drum, and while so doing a failure occurred in the plate. The drum opened up along a length of about three feet, and a thin sheet of water was discharged through the crack. This sheet of water came out with such intense force that the man standing close up to the drum was cut in two, as though with a knife. Had the shell opened up wide the man would have been washed off his feet but the pressure would have been relieved so quickly that nothing very serious could have happened. In this case, the crack was probably not much more than one quarter to three-eights of an inch wide, and the man's body caught the force of the water right as it left the drum with the full pressure behind it.

We have never before heard of such a case, and trust that we never shall again.

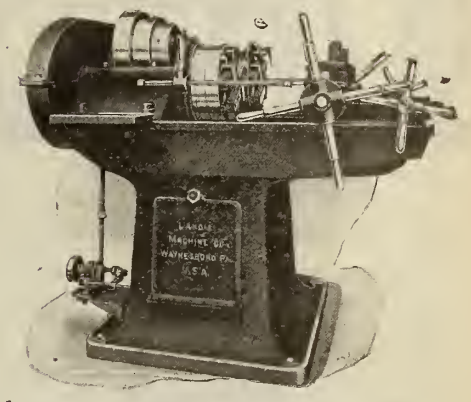
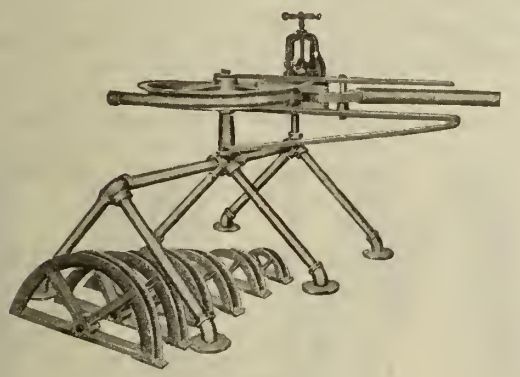
Our Question Box 34

Landis Bolt and Pipe Threaders have a world-wide reputation for reliability and accuracy



Landis Bolt and Pipe Threading Machines do better work more cheaply—and in less time—because of the distinctive design of the Landis Chaser, which operates in the same manner as a lathe tool. Placed at a tangent to the work, the bearing and friction on the cutting edge are at a minimum, allowing the machine to be operated at a higher speed than is possible when a hobbed type of die is used.

These features are contributive to economical production and explain, in part, why Landis Thread-Cutting Machines are considered standard equipment by leading manufacturers, whose hardest jobs they handle with complete satisfaction.



Pipe Benders

Here is a machine that bends all sizes of pipe, generally used, to any required degree easily, quickly, surely. It bends the pipe cold and does not weaken the metal or open seams. The "Wonder" Pipe Bender is so economical that the smallest shop may have one. Operated by unskilled workmen, it will bend a two-inch pipe to a 90-degree angle in less than a minute. Unlike an elbow joint, a perfectly bent pipe offers no obstruction to the flow of steam or water. Other Wonder Machines handle pipe and tubing from ⅛″ to 8″ in diameter.

We are the sole Canadian Agents and our nearest Sales Office will gladly send detailed information of special interest to purchasing agents.

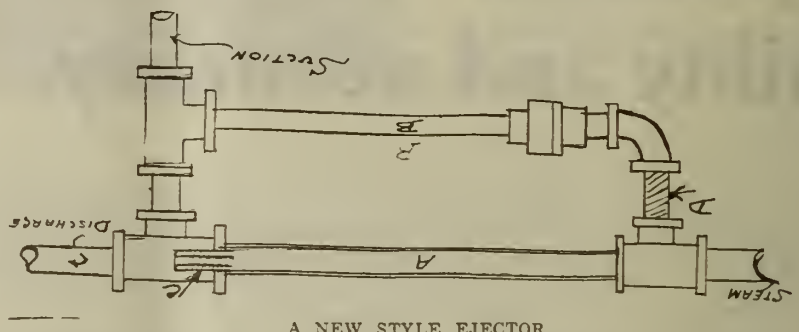
The Operators' Point of View

PUMP SUCTION AIR VESSEL

Much has been written about solving pump troubles, but a feature seldom referred to is the proper location for suction pipe air vessels. In many cases these vessels are placed on the pipe "B" between the pump and the source of supply. It would seem that better results would be obtained by placing the air chamber beyond the pumps, as shown in Fig. 1. An air chamber so placed would have a better chance to check a suction pound than if placed elsewhere as the primary lines of force of the moving water would have a tendency to move past the pump and be cushioned on the entrapped air in the chamber. Possibly a long bend elbow used in place of the tee at "C" would give improved service.

DESIGN FOR EJECTOR

The ejector shown at Fig. 2 has some features not usually found in such apparatus. It can be made in any convenient size. Pipe "A" is a piece of extra heavy pipe threaded internally at one end to take in the piece of iron rod shown. This rod has a hole drilled through it for the steam jet, the diameter of the hole being in accordance with the size of the ejector pipe. For an 1¼ ejector pipe the diameter of the nozzle should be three-eights inch. The piece "D" is also solid. The steam and suction pipe can be flexible, and the ejector can be handled wth comfort by the pipe "B," which also acts as a sort of suction air chamber.

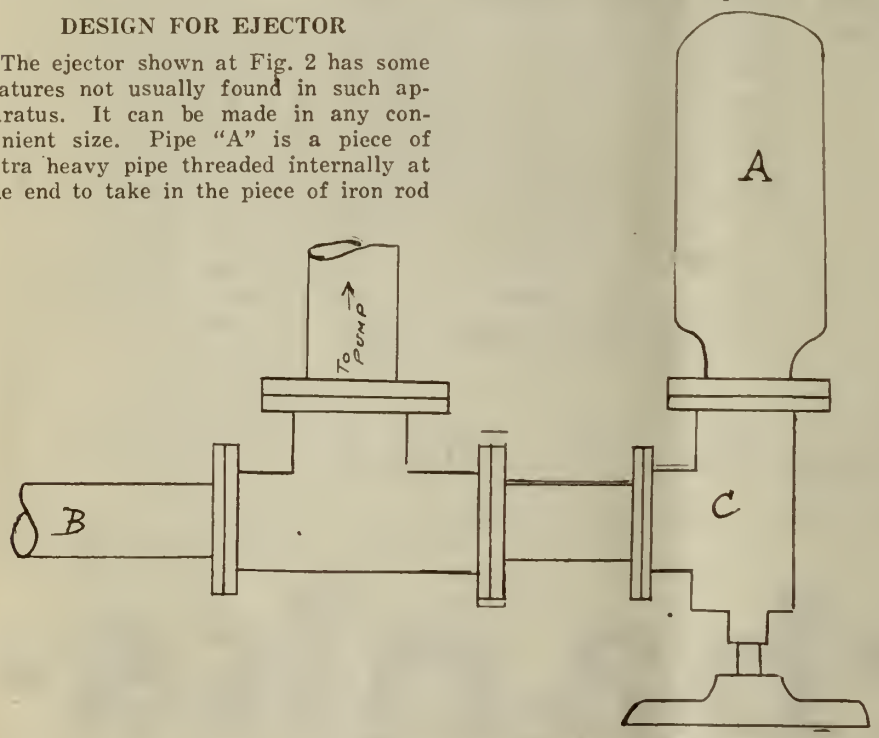


A NEW STYLE EJECTOR.

CHIMNEY CHECK VALVE

The usual cure for a smoking chimney in a domestic furnace is to increase the length of the chimney. The method illustrated here is a departure from the usual, and gave successful results. As a rule, a down draft is only of a few second's duration, though in that time a goodly amount of smoke is forced through the house. The down draft may only occur at infrequent intervals.

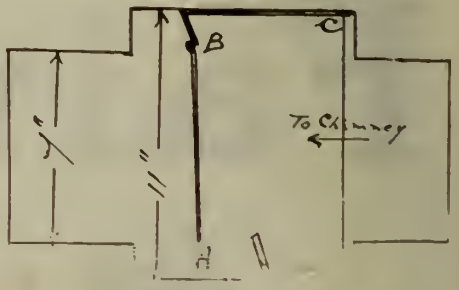
Fig. 1 shows the down draft cure. It is made from stove pipe or galvanized iron. The space around "A" is open and has enough area to allow free exit for the products of combustion. The hinge at "B" is made very slack, to allow perfect freedom of movement, and the furnace pipe can be taken apart from the casing. In the event of a down draft occurring the flap will close, checking the down draft and preventing the smoke being blown out of the furnace. This check, if it achieves the results claimed by the maker, should be a lot less expensive than building an extension on the chimney.



ARRANGEMENT OF SUCTION AIR VESSEL.

REPAIRING PUMP VALVES

Having occasion to repair a pump, I found the valves at the water end in very bad condition. It being impracticable to take them out, it was necessary to find a means of facing up the seats while in place. To do this I took a smooth file, broke a piece about 3 inches long off it, softened it, and made a square hole to take a shank. This shank was made to fit a common brace. The file was then turned round on the seats, and after taking a preliminary cut, another piece of file was used with the edges ground off like a scraper.



CHIMNEY DRAFT CHECK

This finished them up, and each seat only took about ten minutes' work, and a perfectly good job resulted.

ERNEST V. BELL.

The Stability of Dunham Standards

The experimenting which determined the principle of the Dunham Radiator Trap ended twenty years ago. Refinements in its appearance have, of course, been made since it was placed on the market, but improvements here and there have only accentuated the ideal principle on which it operates.

The basic principle of the Dunham Radiator Trap is one involving the laws of thermodynamics. The permanency of this principle makes unnecessary any juggling with the purely mechanical side of the trap.

Permanency in mechanical construction is vital also. The best proof we know of is that furnished by eighteen-year-old Dunham Traps operating to-day, with promise of keeping at it indefinitely. Much of that can be credited to the honest craftsmanship of eighteen years ago—and to this standard we adhere to-day, in what is said to be one of the finest industrial plants in Canada.

In using Dunham Radiator Traps and other Dunham products, you place your confidence in standards that have matured, that will never be sacrificed to commercial expediences.

Full details of the Dunham Trap, and the other Dunham specialties, will be sent on request.

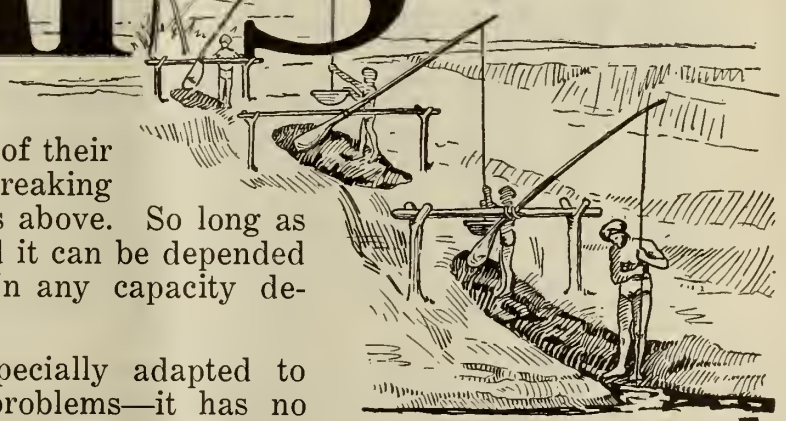
PUMPS

The Egyptian Shadoof relays the water of the River Nile from one well to another until the heights above are reached.



Just as long as the dusky Egyptians continue to dip, dip, dip—to the tune of their monotonous "pumping" song—the creaking Shadoof carries the water to the hills above. So long as an **American-Marsh** Pump is operated it can be depended upon for splendidly efficient work—in any capacity desired.

The **American-Marsh** Pump is especially adapted to the solution of difficult pumping problems—it has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design.

I ordered the genuine "Palmetto" Packing and the Purchasing Department has sent me this cheap imitation.

WHY DID THE ENGINEER ORDER "PALMETTO"?

Because he knew that it gave such long service even under hard conditions, and it would save him unnecessary labor and make for operating economy.

WHY DID THE PURCHASING DEPARTMENT SEND AN IMITATION?

Because they could buy it for less money and failed to take into consideration the greater quantity used and increased labor expense of frequent repacking.

Buying on price rather than quality is usually expensive in the end, especially so of packing, as the labor expense of applying it is much more than the cost of the packing itself, so that the quality that gives long service saves labor expense and is therefore more economical.

The Purchasing Department makes a great mistake when it fails to buy on a quality basis.

If you don't know "Palmetto," let us send you free working samples to test for yourself.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

EQUIPMENT

STEAM ENGINES, BOILERS, HEATERS, tanks, stacks, pumps and condensers, transmission and elevating machinery, safes, vaults and vault doors; catalogue and specifications sent on request. Apply, mentioning "Power House," to Goldie & McCulloch Co., Ltd., Galt, Ont. (pfh)

PORTABLE BOILERS—LOCOMOTIVE TYPE, on wheels, each 15 horsepower, with engines mounted on boilers; can get Government certificates for 90 and 100 pounds working pressure; cheap; also 40 horsepower, high speed Leonard automatic engine. Apply, mentioning "Power House," to Henry Engineering Co., 71 Bay Street, Toronto. (pfh)

BOILERS AND POWER PLANT EQUIPMENT bought by the Henry Engineering Company (Henry-Rumgay-McBryde), 71 Bay St., Toronto. Mention "Power House." (pfh)

EMPLOYMENT DESIRED

POSITION WANTED BY AN EXPERIENCED refrigerator engineer, also competent in ice making and electricity. Address, D. M. J., Power House, Toronto. (p1h)204

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers. Corliss and all classes of stationary engines, compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St., Toronto. (pfh)

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House. (pfh)

NON-CORROSIVE CYLINDER OIL

MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 242-244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,

New York, U.S.A.

Chimney Repair Work

The Broad Face Gives Endurance

THE unusually broad face of the segment and the corresponding broad face of the pinion reduce wear on the teeth to a minimum in American gauges.

The segment itself is made of specially hard cast bronze, while the shafts and bushings of both segment and pinion are made of the same wear-defying metal. Both segment and pinion shafts also rest in phosphor bronze bushings to further reduce wear.

AMERICAN IDEAL STEAM TRAP

All the way through they are built to withstand the most exacting service.

Which is another way of saying that these accurately constructed gauges RETAIN THEIR ACCURACY long after ordinary gauges are worn out.

Another thing that insures ACCURACY is that each dial is hand-calibrated—each one designed particularly for the gauge on which it is applied.

May we send you a copy of Catalog No. 70.

Extravagance Must Stop!

THE COPES Boiler Feed REGULATOR

is a vital organ in the system which draws the latent energy out of the coal pile and delivers it at the bus bar or the main drive shaft.

Without the Copes Boiler Feed Regulator none of the other organs can perform its function properly. Stokers, feed water heaters, water softeners, and the boilers themselves cannot do their best without proper feed water regulation. The legibility of steam and water flow records, pressure and temperature charts, all depend more or less on scientific feed water regulation.

For complete information about COPES BOILER FEED REGULATORS, ask for Bulletin D.

Check the Dollars You Burn!

Do you know how many of the dollars you burn are actually invested in heat—and how many are wasted?

Of course you know how many tons of coal you buy. And you probably know how much heat that coal contains—you can get a B.T.U. analysis from any chemist. But do you know the amount of heat you get out of that same coal?

There is only one dependable way to calculate the value of your coal—what quantity of water is evaporated by a ton of it? A

YARWAY-LEA V-Notch METER

will give you the records you need to determine the degree of economy with which your boiler room is operated and will enable you to prove this to the management. It is a simple, durable, scientific machine, providing permanent records guaranteed accurate within 1½% at high and low rates of flow.

There are many other uses for the Yarway-Lea Meter beaidea in the boiler room.. Booklet L-40 goes into details. Where shall we send your copy?

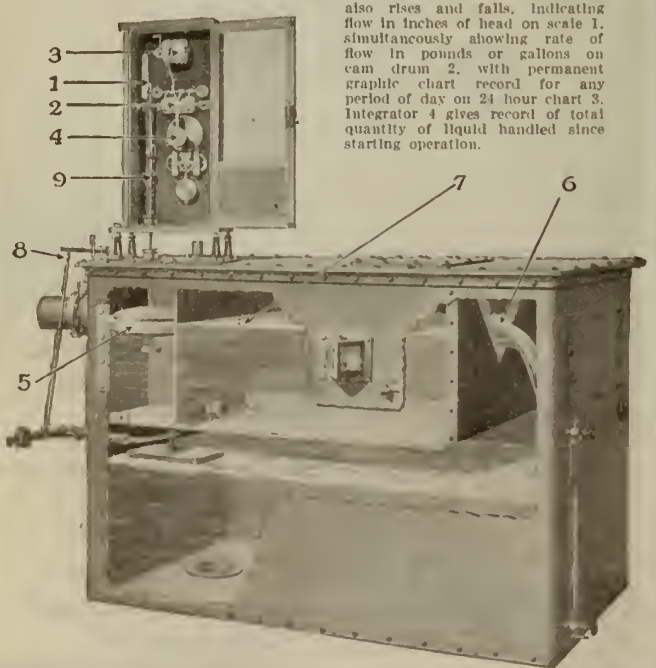
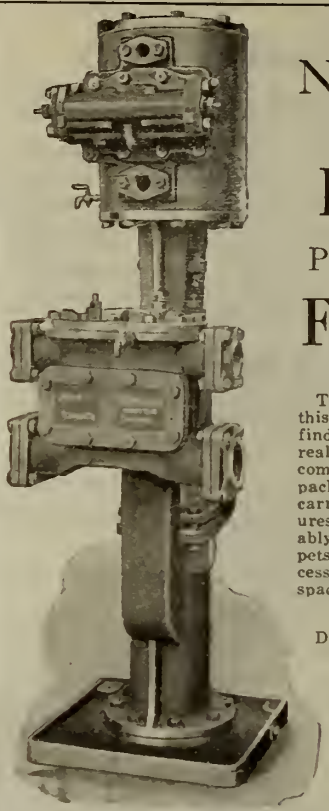
YARWAY-LEA V-NOTCH METER

Operation: Liquid is admitted through control valve 8 to weir chamber 7. As liquid rises and falls, V-notch 6, float 5 connected to rackrod 9 also rises and falls, indicating flow in inches of head on scale 1, simultaneously showing rate of flow in pounds or gallons on cam drum 2, with permanent graphic chart record for any period of day on 24 hour chart 3. Integrator 4 gives record of total quantity of liquid handled since starting operation.





NO EXCUSES
With the
HEPBURN
Patent Vertical Ram
FEED PUMP

There are no excuses attached to this Hepburn Patent Pump. You'll find that out if you give it some real work to do. It is a sturdy, compactly constructed, outside packed type for Feeding Boilers carrying the highest steam presures. The construction is remarkably simple and eliminates all tappets and levers. Every part is accessible, and it takes little floor space in the Power House.

Duplex Pumps, Vertical Engines, Compressors, Hand and Electric Overhead Cranes for Power House Service are also products of the Hepburn plant.

As Easy as Renewing a phonograph needle

Would you buy a phonograph, so constructed that it required an expert mechanic to take it apart every time it needed a new needle? Then why put up with valves that require removal from the line, or at best call for considerable skill, tools and devices, whenever the disc becomes worn from hard use?

It takes but a minute or two to replace a worn disc in a PRATT & CADY RENEWABLE DISC GLOBE VALVE. In a jiffy you unscrew the bonnet and slip a new asbestos disc onto the end of the spindle. The very simplicity of construction adds rugged atrength and long life to Pratt & Cady Valves and Renewable Discs. Here is a sure way to reduce your maintenance costs!

Learn more about it. Send for our free valve book.

Garlock Packings

Have you ever considered the loss in engine efficiency due to excessive friction on piston and valve rods caused by the use of inferior and poorly lubricated packing?

A horse power easily can be absorbed at the stuffing box and, when considered in dollars and cents at the coal pile, the loss would pay for a high class packing many times over.

Garlock packings are designed to meet every condition of service.

Write for Catalog.

The Garlock Packing Company

Hamilton - - Ontario

BRANCHES:

M ontreal, Quebec.
Toronto, Ontario.
Winnipeg, Manitoba.
Calgary, Alberta.

Lascar V Packing

CONSISTS of a single V-shaped bar of white metal securely fastened in its cushioning of highest grade asbestos. The packing is extremely flexible and exactly takes the shapes of all rods, and having a continuous bearing surface of white metal reduces friction on the rods to a minimum. This packing is particularly adapted for the highest steam pressures and has the advantage of great durability, consequently saving much time and labor in constantly replacing glands.

Made in sizes from 5/8" up.

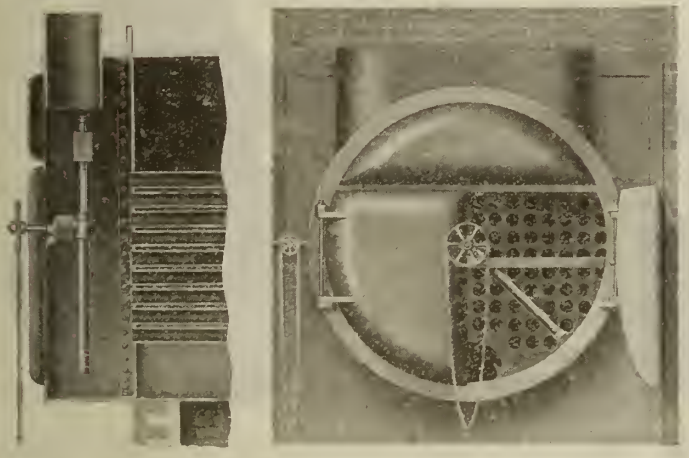
The appalling waste of coal in the operation of Return Tubular Boilers



Some years ago the Engineering Department of the University of Illinois conducted a test of Vulcan Soot Cleaners in Return Tubular Boilers.

For 5 days they allowed soot to accumulate; then 5 when tubes were cleaned daily; then 5 more of no cleaning. The result of that test was conclusive evidence that most Return Tubular boilers, not equipped with soot cleaners, waste an appalling quantity of coal.

The test showed an increase in evaporation due to clean surfaces of 13%. It indicated a DECREASE in coal burned per square foot of grate per hour, due to clean surfaces, of 32.16%. It showed a lowering of stack temperature, due to clean surfaces, of 17.59%.

It is plain that maximum evaporation and minimum coal consumption don't go together when the tube surfaces are heavily coated with soot—a perfect insulator, the most efficient dissipator of heat known! It is obvious that the soot must not merely be removed OCCASIONALLY, as is done with the hand lance, but REGULARLY, at stated intervals, as is done by the Vulcan Cleaner. Without this regular cleaning, soot has time to build up, retard evaporation and increase coal bills.

The owner of Return Tubular boilers that are not equipped with Vulcan Soot Cleaners may take it for granted, therefore, that he is paying for this equipment many times over yearly in lowered efficiency and unnecessary coal wastage.

Ask for a copy of our folder "SPENDING $796 TO SAVE $1,017.40." It is a revelation to the plant owner and engineer of the tremendous possibilities of Vulcan Soot Cleaners as dividend-paying producers.

BAILEY Boiler Meters

Simple Yet Comprehensive

For efficient operation the Steam Flow and Air Flow records come together and show as a single record. When excess air is entering the furnace, the Air Flow record shows above the Steam Flow. The opposite is true when the coal feed is too great and the fires are not receiving sufficient air.

The record of the Flue Gas Temperature made on the same chart indicates the relative condition of the baffles and tubes. The Fire Box Draft is indicated for assistance in maintaining balanced draft conditions.

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

LEONARD

STOP !

Don't Throw Away Your Fuel

In the average power plant one shovel of coal in five is wasted. One-fifth of all the fuel burned under boilers operating on saturated steam is thrown away without getting the full value out of it.

Repairs, replacements, labor and similar items involve the expenditure of thousands of dollars annually; an expense that should be reduced and which can be reduced by the application of

ELESCO SUPERHEATERS

ELESCO Superheaters save fuel—often one shovel in five. They reduce maintenance costs by increasing boiler capacity, making possible the operation of boilers at lower ratings. Water hammer with its destructive costly repairs is eliminated, because superheated steam, being dry, carries no water into steam lines and engine cylinders.

An estimate of what ELESCO Superheaters will accomplish in your plant will disclose savings which you may never have considered possible—savings which will return the first cost of the installation in a few months.

May our engineers assist you?

Have you a copy of Bulletin NT-7. If not, send for it to-day.

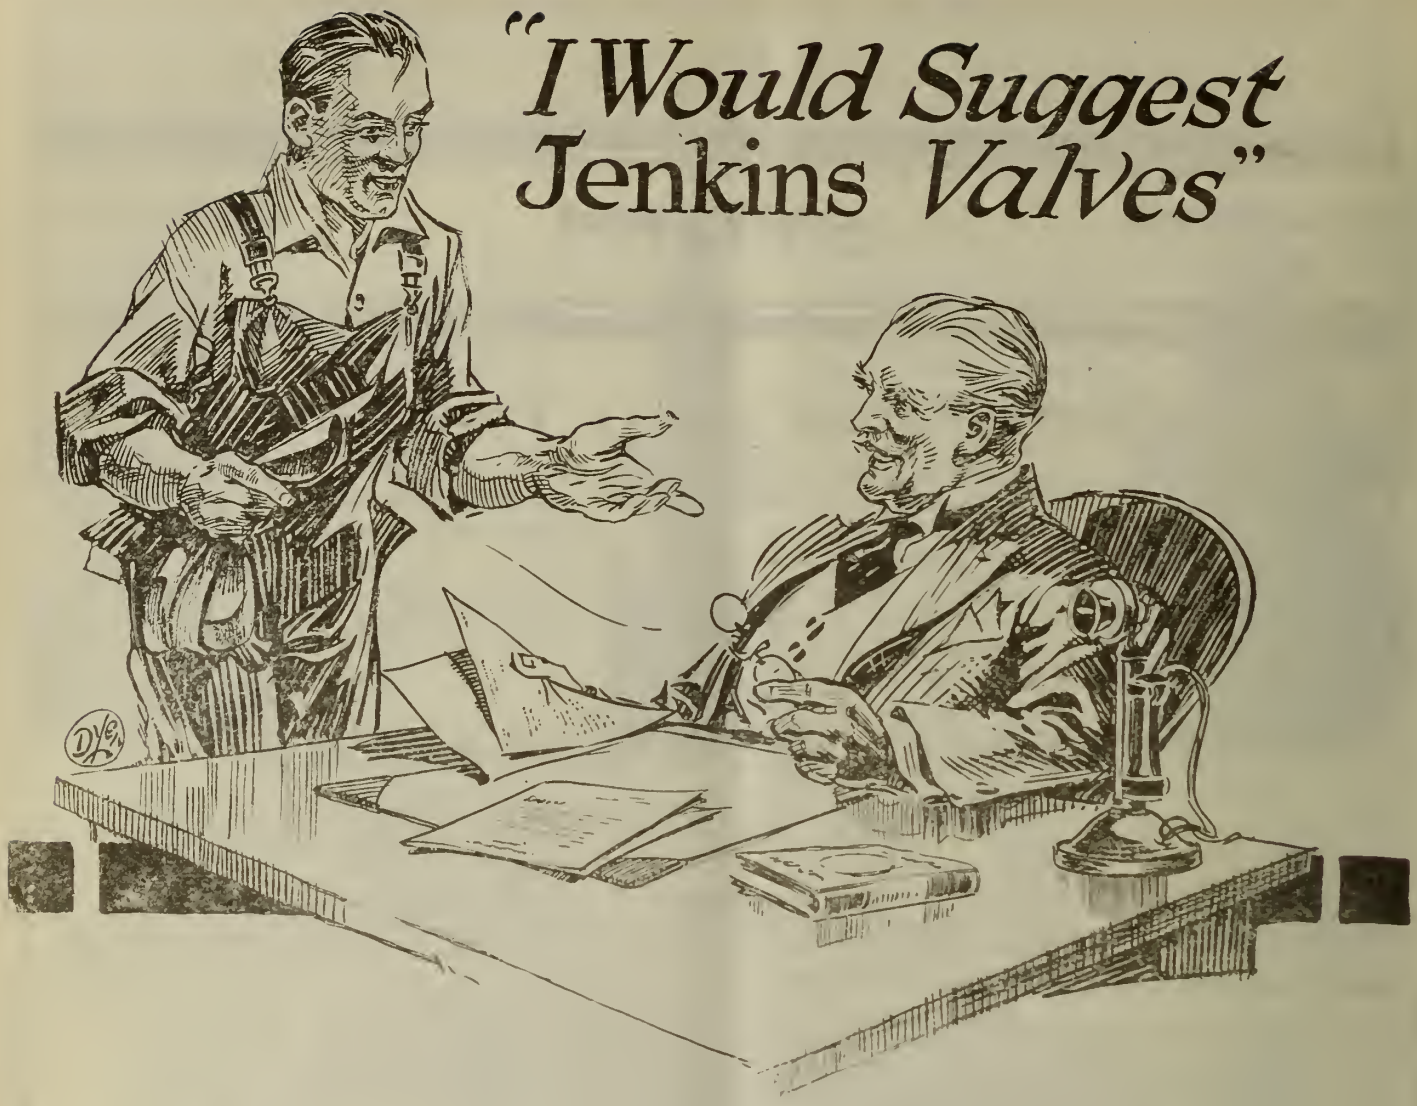
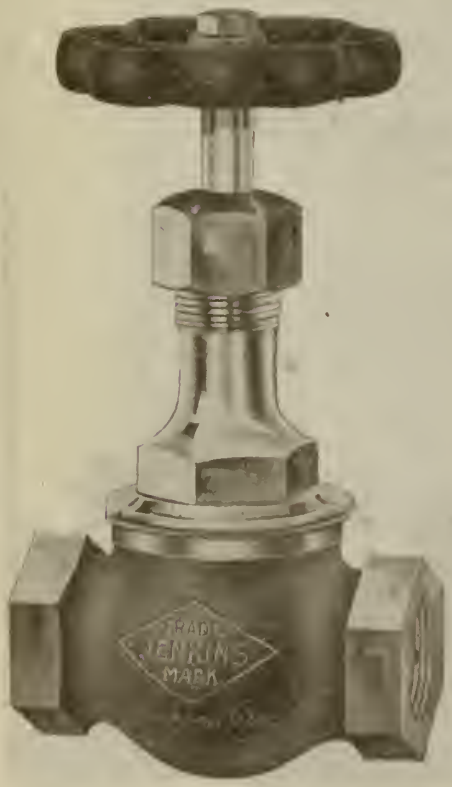
"I Would Suggest Jenkins Valves"





WHEN the inevitable breakdown—occasioned by inferior valve equipment—occurs, the Engineer who knows valves and valve requirements will invariably suggest Jenkins Diamond-Marked Valves.

Unpleasant reminders do not follow the installation of Jenkins Valves. Made strong and heavy and made of the best brass, iron or cast steel, they remain dependable and unaffected when subjected to the strain of hard usage and severe service.

Jenkins Diamond-Marked Valves are made in a size and a style to completely control the passage of steam, water, air, gas and other liquids or vapors.

Obtainable at supply houses everywhere.
Catalog No. 8, describing the entire line, free on request.

Diamond Soot Blowers Mean Greater Profits

THE big industrial plants of the country are operated for profit. Although they render a service of great importance to the entire population, their very existence, to say nothing of their growth and development, depends upon their ability to pay dividends on the capital invested in them.

This means that every phase of their operations—buying, producing and selling—must be carried on in the cheapest manner compatible with the character of the business. The big corporations scrutinize every operation with reference to its relation to dividends. This is particularly true to-day with regard to costs of power.

Cheap power means cheap factory costs. Cheap factory costs mean reduced overhead. Low overhead increases profits. Every dollar saved in the coal pile means an appreciable addition to the dividend pile.

Almost without exception the big industrial plants are increasing dividends through the use of Diamond Soot Blowers. They have found that Diamond Soot Blowers effect such economies as—a saving of 4 to 8 per cent. in fuel—increase in boiler efficiency of 3 to 4 per cent.—a material saving in labor, labor turnover, etc.

Among the important big industrial leaders who are saving money with Diamond Soot Blowers, are such concerns as:

General Electric Co.
Eastman Kodak Co.
Burroughs Adding Machine Company
West Virginia Pulp & Paper Company
Procter & Gamble
American Rolling Mills Company
Pressed Steel Car Co.
Lukens Steel Company
Swift & Co.
Cluett, Peabody & Co.
Pierce Arrow Motor Car Company
Stanley Rule & Level Company

If your boilers are not Diamond-equipped, your first step in the reduction of power costs is a general move in the direction of a telephone or stenographer.

Our district offices are listed in the telephone books of all principal cities. If you write us direct, ask for Bulletin No. 280.

SOOT BLOWERS - SAVE 4 to 8% FUEL

A NEW EFFICIENCY DEVICE

The Time Punch for Columbia Recording Thermometers

You can now order your fireman, operator or night watchman to keep a sharp eye on temperature variations in any heat-treat process, or for heat regulation in operating efficiency—*and by instructing him to use the TIME PUNCH at stated hours or minutes* YOU CAN BE SURE THAT YOUR ORDERS ARE CARRIED OUT.

The TIME PUNCH makes a small hole in the time border of the chart *the very second the button is pressed.* It makes the Columbia Recording Thermometer *a time clock* as well as a heat-recording device.

No chance now for the employee in charge of heat-regulation to shirk or misrepresent. The little punch hole tells you whether or not he has been on the job. If he doesn't "ring up" at regular intervals, those tell-tale marks will stand against him. Side by side with the graph line that indicates temperature fluctuations are the indelible marks that tell you whether he has or *has not* been attending to his duties.

By checking up on the individual who is responsible for proper heat regulation, you can be pretty sure that he will not permit the line to waver.

The TIME PUNCH makes the Columbia Recording Thermometer doubly valuable. The chart gives you a 24-hour record of temperature changes. The TIME PUNCH, by compelling vigilance on the part of the operator, gives you the assurance that definite instructions as to temperature will be carried out! Its use is your protection against losses mounting up to hundreds and perhaps thousands of dollars.

This new TIME PUNCH is also supplied on Columbia Recording Gauges and Tachometers.

Send for Recording Thermometer Catalog H-33

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract. Readers are requested to advise the publishers regarding any equipment that they are buying and that is not listed.

Stays Tight

THE ANDERSON
Model "D" STEAM TRAP

Absolutely prevents the loss of live steam and resulting hold-ups.

The Anderson Model "D" Steam Trap gives efficient, economical service. It automatically drains the condensation from radiators, steam coils or heating systems without reducing pressure in the slightest. Three inches of water seals the valve and seat, so when condensation is exhausted no steam is allowed to escape.

If you are troubled with condensation problems, our catalogue will help—a post card brings it.

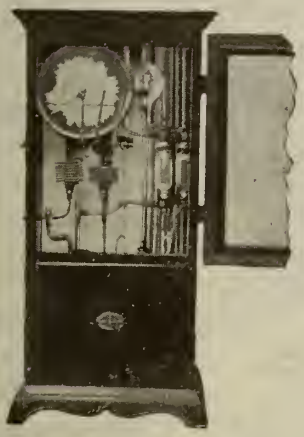
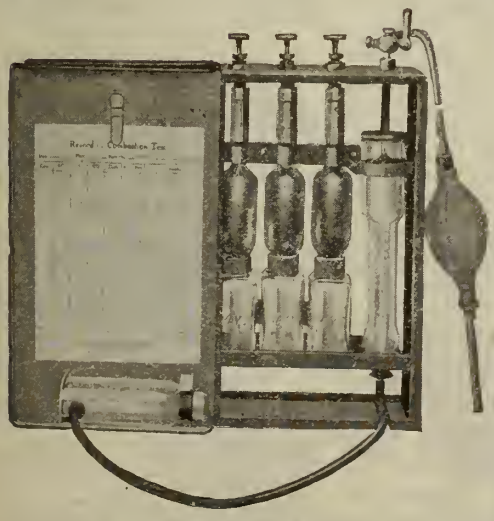
The Hays Draft Gage



The Hays Automatic CO_2 and Draft Recorder

Awarded Certificate of Merit by Franklin Institute.



The Hays Improved Gas Analyzer.

Find the Errors and Correct Them

The way to stop waste of coal is to go to the boiler room where most of it is wasted and eliminate the wasteful practices in operation. Some of them you can see at a glance and stop at once, but there are other persistent hidden ones which you may never suspect until you see their effect, and will never do away with until you have means of knowing of their presence. A Hays record of the draft over the fire and the CO_2 content of flue gases will point out clearly when and why your coal is being wasted and enable you to build up your furnace efficiency.

The Jos. W. Hays Corporation

Combustion Efficiency Appliances

1040 E. 8th St., Michigan City, Indiana

Leaky boiler settings, improper relation between draft and fire thickness, improperly timed firing periods may all sound innocent enough until you realize that they are the very source of coal waste.

You cannot better your conditions until you know what your conditions are

Hays Apparatus

gives you the complete story

This one car of insulation will save 742 cars of coal

The Proof:

The life of a felted insulation like Asbesto-Sponge can be conservatively figured at twenty years. A standard 36 ft. car carries 1680' of 8" and 1680' of 4" pipe insulation packed inside the 8"—thickness 1½". With steam pressure at 100 lbs. and air temperature at 70° the efficiency of the 8" is 90.3% and the 4" is 88.9%, thus saving in 20 years 37,100 tons of coal or 742 fifty-ton cars. Savings on Johns-Manville 85% Magnesia can be similarly predetermined.

Other insulations for other services: Asbestocel, Zero, Anti-Sweat and Ammonia Insulation. Underground Conduit Insulation and Insulating Cements.

WHEN you see men handling insulation, you need not wonder what they are going to do with it—you know they are going to SAVE FUEL — and furthermore, you can know exactly *how much* fuel they will save—for the hit-or-miss stabs of the old "pipe covering" days have given way to a modern science of insulation for pre-determining saving and applying these figures in cost of power in the plant or heat in the home.

If coal were cheap and easy to get—and insulation were expensive and hard to get—then bare steam surfaces or plain pipe covering might be countenanced. But in times like these, INSULATION is a vital thing.

The heat losses through pipe covering you may have installed in the days when you didn't need to get down to brass tacks in saving fuel can be figured for you. Such figures compared with Johns-Manville charts will point out the difference between what heat you now save and what you can save through the most efficient commercial insulations obtainable—whether it be Johns-Manville 85% Magnesia of the molded type or Asbesto-Sponge of the strong built-up Felted Type.

Figures shown at the left indicate the millions of dollars saved by Johns-Manville Insulation Service in determining the insulation that is right for you—and applying it for you in the right way.

PRESTIGE

The steady, confidence-inspiring service of 65,000 Weir Pumps, all over the world, is daily maintaining the international prestige of all products marked "Weir."

Watch a Weir Pump at work. Its slow, even, powerful strokes will convince you that it is accurately designed and properly made for long, efficient service.

In addition to Weir standard pumps there are a large variety of designs for special duties. For high duty installations, for water or oil, we can supply special patterns, simple, compound or triple, for pumping against pressures up to 1,000 pounds per square inch.

Special attention is paid to the prompt dispatch of goods and the routing and shipment of all consignments. Special instructions in this regard always receive our most careful attention.

Prompt and careful shipment is but a single phase of Weir Service. To serve our customers in every way to the best of our ability is our aim.

How to Test Advertising

THE man who doubts the power of advertising belongs in the same class with the man who refuses to believe that the world is round simply because he can't get off somewhere at a distance and see its roundness for himself.

The merchant who fears to attempt advertising because he figures it as an "expense" is blind to his own interests. I personally know several men who, because they once tried advertising to the extent of a cheaply printed hand-bill and didn't find it necessary next morning to call on the police to keep the crowds of eager buyers from swamping their store, loudly and solemnly aver that "advertising doesn't pay."

Advertising *does* pay.

The most successful merchants are the merchants who believe most thoroughly in advertising, and who practice their belief.

But advertising, in order to pay, has got to be *intelligent* advertising.

The day of hashed-over superlatives — "best goods," "lowest prices," "best stock in town," "greatest bargains ever heard of," and so on—has passed.

People have learned to distinguish the *truthful* advertiser from the blatant behind-the-times storekeeper who believes that, so long as *he* claims to have the best goods on earth, or under the earth, or within wireless distance of the earth, people will break their necks trying to get to his counters in the forefront of the crowd.

Put some *brains* into your advertising.

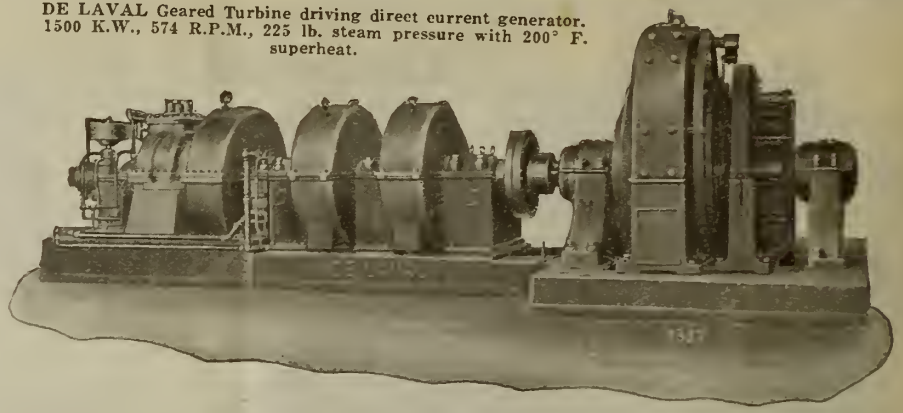
Don't let the office boy write your announcements in between his other duties.

Don't doubt the business-getting and business-building power of intelligent and informative publicity — and you will find that advertising *does* pay.

—*Jerome P. Fleishman.*

Steam Turbines *for* Driving Pumps, Generators, Shafting, etc.

DE LAVAL Geared Turbine driving direct current generator. 1500 K.W., 574 R.P.M., 225 lb. steam pressure with 200° F. superheat.



With alternating current distribution, speed variation for individual machines is difficult, but with direct current, each machine can be speeded according to requirements, thereby increasing the output to the maximum. For the operation of elevators, etc., direct current is indispensable.

A direct current generator geared to a De Laval steam turbine forms a simple, reliable and efficient unit.

If alternating current is required, as for transmission to a distance, there are many advantages in using a standard low speed alternator, as it is more simple and more reliable than a high speed alternator and can be taken care of and repaired by ordinary operating men. By the use of the De Laval double-helical speed-reducing gear, the turbine can run at the most efficient speed.

The De Laval double-helical speed-reducing gear makes the turbines available for driving slow-speed machinery as pumps and fans, also for rope and belt drives. The turbine is simple, easily cared for, requires few supplies and little attendance, and may be installed in limited space without expensive foundations. It maintains a good steam economy indefinitely.

Heavy overloads are carried at reduced steam pressure without distress or harm, merely by opening more nozzles.

Where there is exhaust steam available from other units more power can be obtained with no extra cost for steam by the use of the De Laval low pressure or mixed flow turbine. Where steam is wanted at low pressure for heating or drying, it can be taken from the exhaust of a De Laval back pressure or bleeder turbine.

"It's A Jenkins—
the Best Valve Made"

Supply men everywhere sell Jenkins Valves with confidence based upon actual knowledge of the trouble-free service which these valves furnish.

Jenkins Diamond-marked valves are made in types and sizes to meet all requirements of service in power plants and wherever else a dependable trouble-free valve is required.

The dominant idea behind the construction of every Jenkins Valve is STRENGTH and proportions for MAXIMUM SERVICE —not merely the average. Every valve is tested in this regard before it leaves the factory.

You'll know a Jenkins Valve by the name "JENKINS" within a Diamond Mark cast on the body. At Supply Houses everywhere.

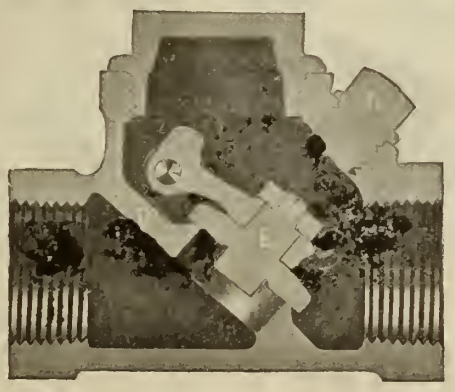
TRADE PENBERTHY MARK.

BE SURE THIS NAME IS ON THE VALVE YOU BUY



CUT NO. 544-A.

SWING CHECK VALVE

Get Away From Check Valve Troubles

by installing

The Penberthy Double Plug Check Valve

on Your Steam Lines

Cut No. 544A shows sectional side view and illustrates to advantage the liberal thickness of metal in diaphragm. (See letter D), also the even distribution of metal throughout. The disc (letter E) is also of liberal thickness, and as same is made of a special wear resistant bronze composition the Penberthy Check is practically indestructible, and will give many years of efficient service. All genuine Penberthy Checks bear our trade mark and the registered pressure 200 lbs., is also cast on each.

The double plug construction makes it possible to take the valve apart if mounted on a wall pipe without disconnecting same from the pipe. The plugs also act as bearings for the disc carrier pin and in case of wear it is only necessary to renew either plugs or pin, making valve as good as new. The top plug "A" is also removable for insertion of screw driver when regrinding disc and seat is necessary.

Stocked by leading jobbers everywhere.

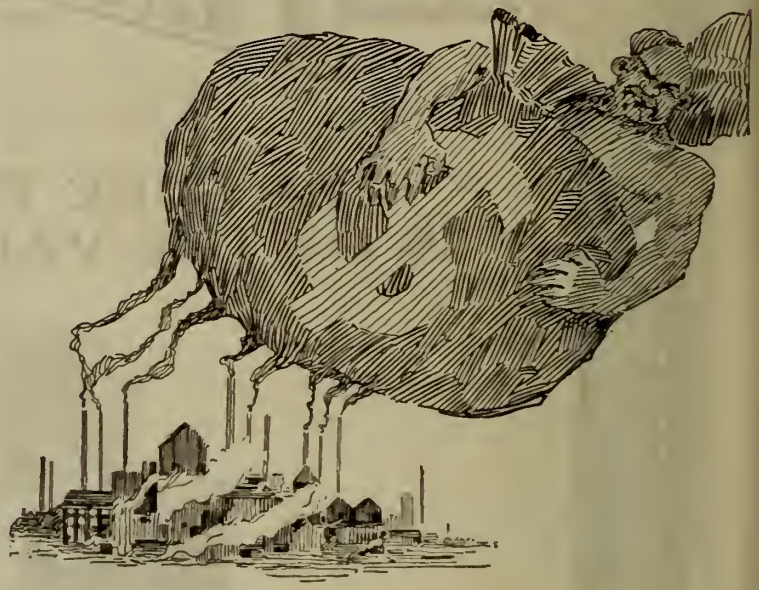
TORONTO - ONTARIO

What is YOUR Contribution?



All smoke clouds are made of money, but not all heat wasted up the chimney can be seen in the smoke. It is excess air escaping into the combustion chamber that carries the heat units up the chimney, cools the gases of combustion, and causes smoke. But

PLIBRICO JOINTLESS FURNACE LINING

stops that waste. Its air-tight, gas-tight construction prevents air infiltration, short-circuiting of gases, and heat radiation. Use PLIBRICO and pay only for the coal you use. Then no cloud of unburned carbon will float away from your stacks.

PLIBRICO is used in every case where laid-up fire brick is used, and with better results. Try it on a front-door arch or wall, or on baffle walls, and the saving effected will demonstrate the greater value of a complete PLIBRICO setting.

We guarantee a saving of time, money and fuel for those who install PLIBRICO.

Shipped in steel containers of distinctive appearance as shown below. Warehouse stocks in all principal cities.

Send for our booklet L 8 on Furnace Building.

Poor Lubrication is Costly

PLANT operators insist upon efficient, scientific lubrication these days. They realize that poor oil is expensive at *any* price.

Imperial Lubricants are especially prepared to meet the modern demand for correct lubrication. There's a grade of uniform-quality oil for each different lubrication requirement of your plant. Supplies are always conveniently available.

Hundreds of firms all over Canada use Imperial Lubricants exclusively. Actual records show a marked reduction in overhead expense and increased capacity throughout plants where Imperial Lubricants are regularly used.

You cannot afford to buy any but the best oils for expensive machinery. Check over the accompanying list of Imperial Lubricants. See how fully it meets every lubricating need.

Imperial Engineers will gladly help you standardize the lubrication of your plant. Write to 56 Church St., Toronto.

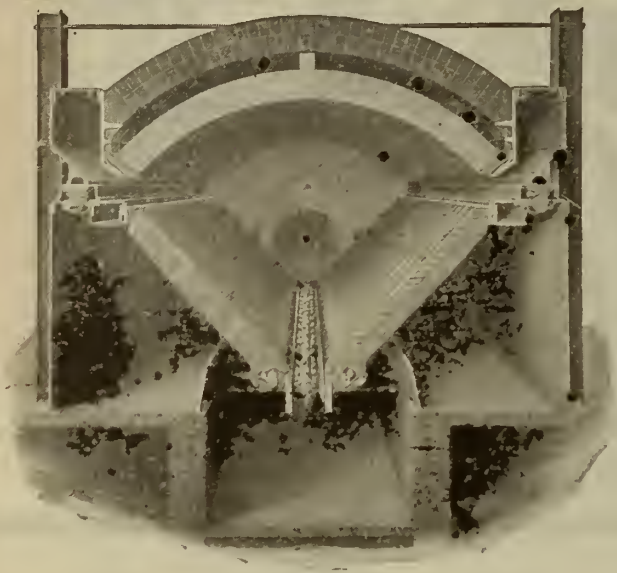
MURPHY
AUTOMATIC
FURNACES



FACTORS BACK OF EVERY INSTALLATION OF MURPHY FURNACES

Natural Draft—On everything except the most extreme peak loads. Will double the output of your boilers without one penny for draft.

Burns Wide Range of Fuels—This is the biggest possible feature for the engineer to consider at the present time.

Standard—The Murphy Furnace is standard in design. All new features produced from time to time may be applied to any Murphy Furnace now in use.

Smokelessness—The Murphy Furnace is designed to afford perfect combustion. The arch insures high furnace temperature, which means that the air is preheated and admitted exactly where and when needed to give maximum efficiency.

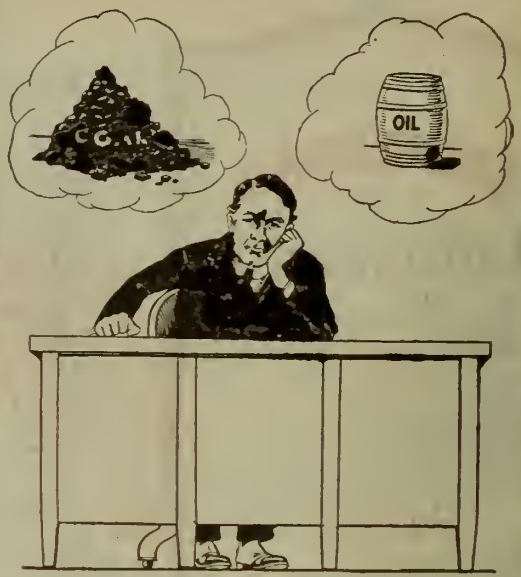
Automatic Operation—The amount of fuel supplied may be regulated while in operation. Every detail for keeping a perfect fire is provided in the design and construction of the Murphy Furnace. The coal is supplied—the fire distributed evenly—the ash removed—continuously and automatically.

Our Catalogue HM-6 shows how Murphy Furnaces can be installed under any type of boiler—50 H.P. and up. Ask for it.

For information on RILEY UNDERFEED STOKERS for large boilers, see last month's advertisement or send for RILEY STOKER Catalogue "HR-6"

MURPHY IRON WORKS
DETROIT MICH. U. S. A.

BUILDER'S VENTURI IRON FOUNDRY



Coal or Oil
Be Sure Which is the Best Fuel for You

Availability of fuel, economy of space, cost and amount of labor, etc.—all enter into the consideration of the advantages or disadvantages of fuel oil as compared with coal in your power plant. However, the factor which invariably figures most prominently in the final decision is **Evaporation Per Dollar Spent For Fuel.**

THE VENTURI
BOILER FEED METER

is practically indispensable in determining **Evaporation**, because it is the most practical, the most economical, and the most efficient means of knowing the rate and method of feeding water to the boilers at all times.

The Function of the **Venturi** remains equally important after oil burning equipment has been installed, because **Evaporation** is still the big problem.

Bulletin 197 is ready. It is yours on request.

High Stack Temperature	**It's Your Money --- Take Your Choice**	Low Stack Temperature
Minimum Steam Production		Maximum Steam Production
Fuel Waste		Fuel Saving
Excessive Labor Cost		Reduced Labor Cost
40% Average Soot Removal by Hand Blowing		95% Average Soot Removal by Vulcan Soot Cleaners

This is the story of Vulcan Soot Cleaners—in a nutshell.
If your plant isn't Vulcan-equipped, your up against the drawbacks listed at the left.
When your boilers are Vulcan-equipped, you're assured of the advantages listed at the right.
Whatever may be the generally good operating conditions of your boilers, it is impossible to maintain maximum results by hand blowing.
It is only through the installation of mechanical soot cleaners—Vulcans—that steam production can be maintained and fuel saved at the same time.
The lack of Vulcan Soot Cleaners in your boilers spells W-A-S-T-E!

Can you afford it?

Let us tell you all about Vulcans and what they can accomplish for you. Please mention type of boiler, steam pressure, and number of tubes high and wide.
Ask particularly for folder "Spending $796 to Earn $1017.40"

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

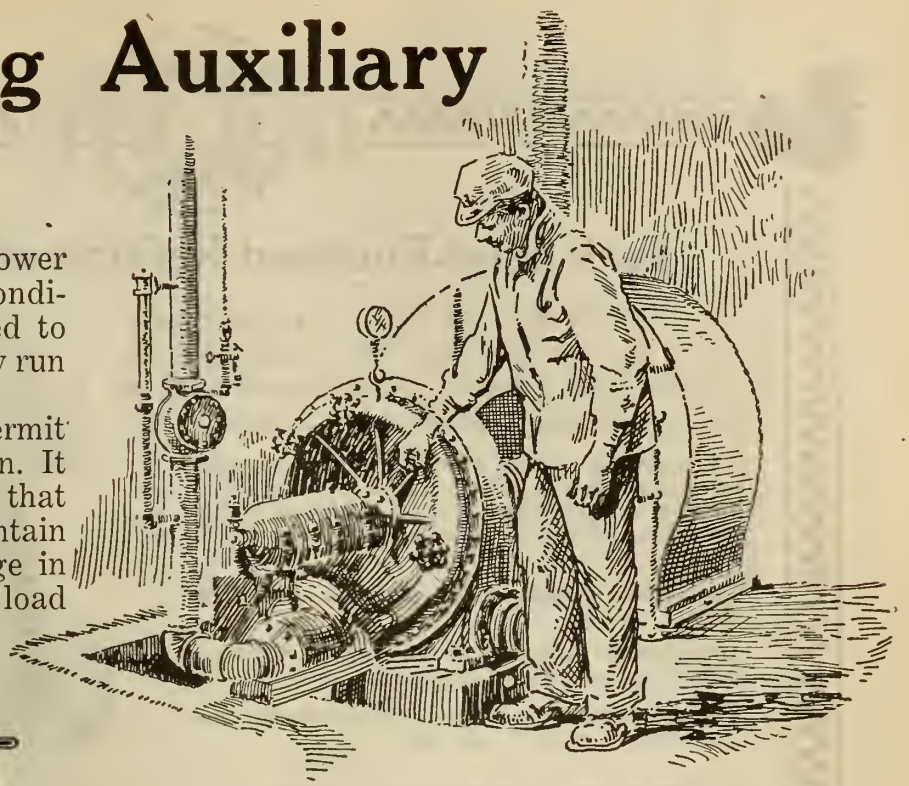
A trial order will convince you of their utility.

DOMINION BELTING CO., Ltd., Hamilton, Canada - Quebec Branch: 51 Duluth Bldg., Montreal

Steam Saving Auxiliary Drives

The auxiliaries in the modern power plant seldom operate under ideal conditions. Most of them are subjected to severe load fluctuations and usually run underloaded.

The high price of coal does not permit extravagance in steam consumption. It is therefore extremely important that the drives selected are able to maintain a good economy over a wide range in load. Operate at nearly full load economy at one-quarter and one-half load.



Sturtevant Steam Turbines are used to drive exciters, boiler feed pumps, house pumps, fire pumps, fans, blowers and special equipment. They combine safety and dependability with high economy under all conditions

Sturtevant (TRADE MARK)

Steam Turbines

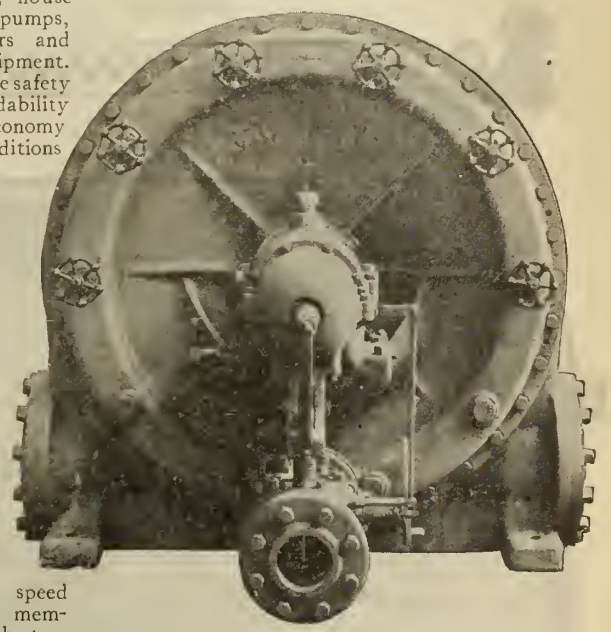
They are not controlled by throttling down the steam, but by shutting off one or more of the several steam nozzles by the hand wheels on the turbine casing. The nozzles remaining in service undergo no change in efficiency.

The turbines are scientifically designed and all parts are constructed accurately to gauge of the best obtainable materials.

The assembly is made under expert supervision and a true running balance is established.

A positively dependable shaft governor holds the speed regulation within close limits and entirely adapts these turbines to drive electric generators.

Consultation with our engineers is recommended before selecting any turbine drive.



When the speed of the driven member is below the turbine speed Sturtevant Transmission Gears are used to obtain maximum efficiency.

QUALITY YORK SERVICE

York Semi-Enclosed Refrigerating Machines

The Raw Water Ice Plant is rapidly taking the lead, and its development demands an Ammonia Compressor that is most economical in Power Consumption.

Where electric current is available at a reasonable cost, our Semi-Enclosed Machine, with direct motor mounting, makes a neat, clean and highly economical plant—no belts, no engine or steam lines.

The machine occupies a comparatively small floor space.

All the power developed by the motor is delivered to the crank-shaft of the machine.

These machines are built in sizes from 30 tons refrigerating capacity upwards.

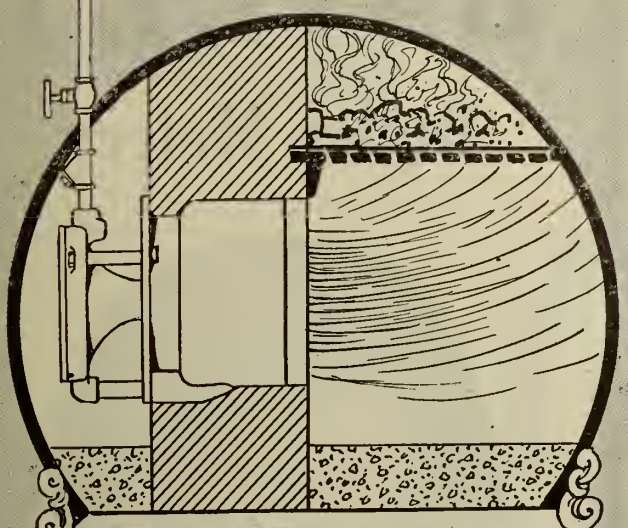
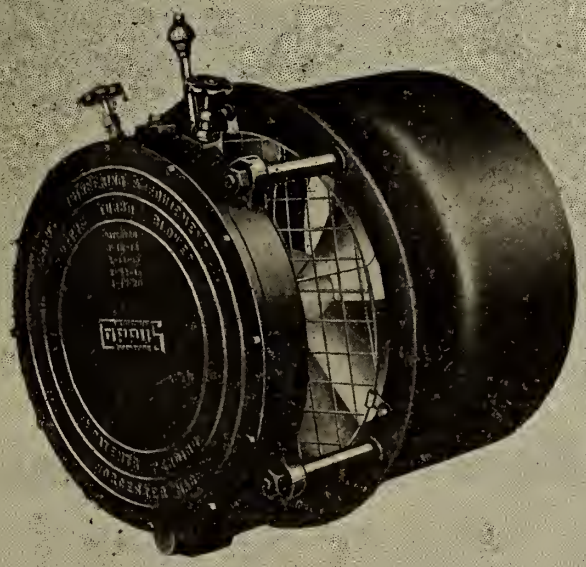
Burn any Fuel



REGISTERED
COPPUS
U.S.PAT. OFFICE

TURBO BLOWER MAKES BETTER COMBUSTION POSSIBLE



Coppus Turbo Blowers make you independent of fuel conditions —you can burn yard screenings, buckwheat coal, coke breeze, culm, slack bagasse, or refuse such as sawdust, shavings, tan-bark, etc., because it provides sufficient draft for complete combustion with any grade of fuel.

A Coppus Turbo Blower forcing air into the ash pit, provides a strong draft through the fuel bed. A turn of the valve shoots steam connected to and turns the fan. to the turbine which is directly Regardless of fuel quality you are provided with the means to make it burn as intensely or as low as you wish.

The Coppus Blower is easily and quickly installed and requires no attention other than lubrication once or twice a year.

There are many other rea ons for Coppus Blower superiority, and they are completely told in our catalogue which will be sent to. you on request.

Coppus Turbo Boiler Feed Pump

This turbine driven boiler feed pump—built as a single unit—supplies a continuous flow of water without pulsation or vibration. No valves to be reground, no water plungers or steam pistons to be repacked, no complicated governing devices to be adjusted.

The Coppus Centrifugal Turbo Boiler Feed Pump responds immediately to peak loads and requires little or no attention due to the automatic and dependable lubricating system—that's why so many power plants have installed them in place of more cumbersome and complicated pumping outfits.

We shall be glad to send you the Coppus Turbo Boiler Feed Pump Bulletin also.

Series 90

It will accurately and consistently deliver any desired reduced pressure to apparatus.

It will also shut off absolutely tight when low pressure is interrupted. Pressure cannot build up on the low pressure side.
Like all other Fisher specialties this valve is distinguished by excellence of material and workmanship.

Actual service in thousands of plants throughout Canada has proven Fisher Power Plant Specialties to be long-lasting and accurate in the most trying and delicate operations.

Ask your dealer or jobber for full information about the Fisher line. Or write for "POWER PLANT SPECIALTIES." It is full of interesting information. We will gladly send you a copy. Write today.

BAILEY

Boiler Meters

Keeping Account of Your Steam Cost

Bailey Boiler Meters not only show the true output of each boiler, but also enable you to keep a continuous check on the furnace efficiency.

The charts record the Steam Flow in red, the Air Flow in blue, and the Flue Gas Temperature in green.

Where stokers are installed pens for recording Wind Box Pressure, and Stoker Speed may be added. Also an indicator for Furnace Draft is provided. In either type an integrator shows the total amount of steam generated by the boiler.

Bulletins upon request.

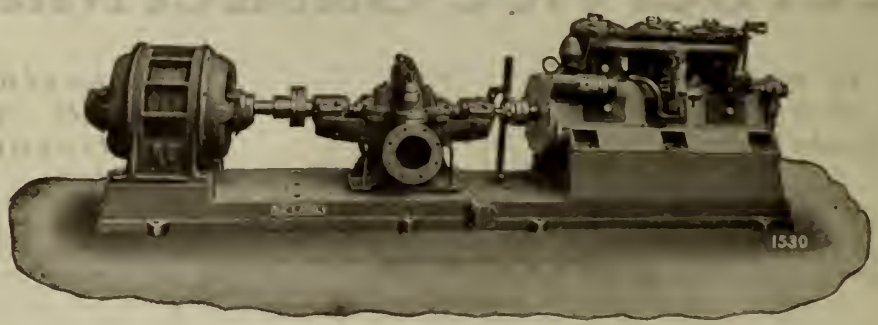
Duplicate Power Supply for Pumping



Ask for our complete catalog B 100

THE eight-inch De Laval centrifugal pump shown herewith is arranged to be driven either by an induction motor, or, when electrical power is not available, by a 6-cylinder 100 horsepower gasoline engine. A clutch is provided for disconnecting the engine when not in use. The unit is rated at 2,100 gal. per min. at 1,160 r.p.m. With a duplicate power supply there is practically complete assurance of being able to deliver water at all times. The characteristics of De Laval centrifugal pumps are ideal for such service, as there is practically zero starting torque and, due to the power-limiting characteristic, the De Laval pump cannot possibly overload the motor.

Simplicity in Design

Jones "A

Low Maintenance Cost

In the operating records of Jones-equipped plants one fact stands out boldly:

Although the Jones "A-C" is the simplest of first class multiple-retort stokers, it meets the most rigid requirements of high-duty stoker firing supremely well.

It continuously sustains the heaviest overloads. It momentarily meets highest peak loads. And because of its rugged simplicity, it does this at lowest maintenance costs as a result of—

No Clinker Formations on Bridge or Side Walls

No Moving Parts in the Fire

Very Simple Operating Equipment

Tuyere Blocks Easily Replaced

No Complicated Power Dumping Mechanism

The maintenance cost of Jones "A-C" Stokers is unusually low because of extreme simplicity both in design and operation. Every part is accessible. There are very few moving parts—none in the fire. complicated power dumping mechanism is used. The fire is automatically kept clean, and accumulated ashes on the balanced dump plates are quickly and easily dumped y hand. The automatic fuel and air controls are subject to independent adjustment and the operation of each retort is under separate control. A perfect fuel bed can be maintained at all times, using any grade of Canadian coal. No clinkers are formed either on the bridge or side walls. This extreme simplicity and accessibility insure the lowest maintenance cost.

These advantages are clearly explained in a new book, "Ten Points of Jones Superiority," just off the press. Have you asked for your copy?'

Established 1907
Published Semi-Monthly

The Power Plant of the Acadia Sugar Refinery

This plant, one of the largest in the Maritime Provinces, has lately made a change in the fuelling arrangements. Oil fuel will be the principal means of steam generation in future.

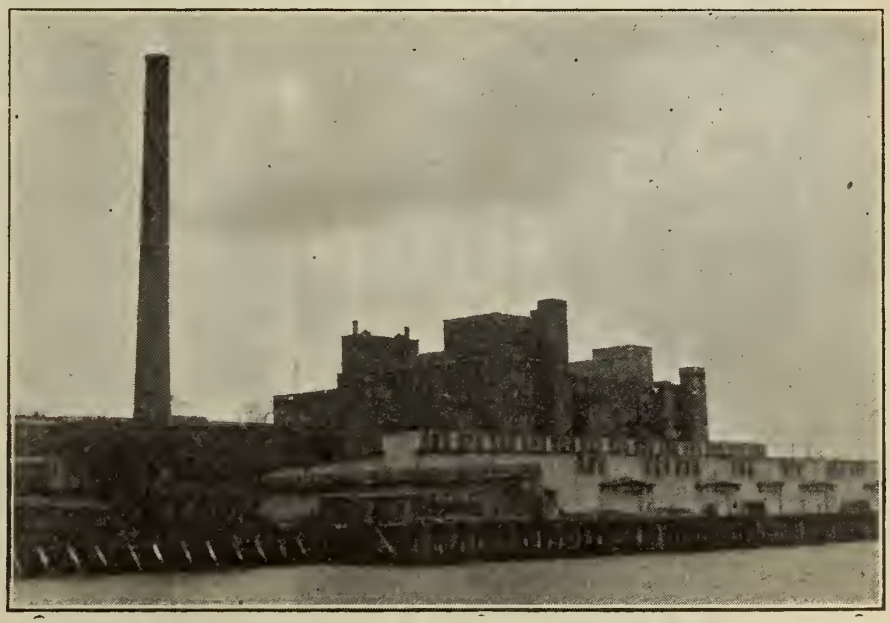
By J. A. McGILLIVRAY

LOOKING back some fourteen years to the time that the Acadia Sugar Refinery was erected, considerable development in power plant engineering practice is noticeable. During that time more attention has been paid to the science of combustion and economical generation of steam than in any other period since steam engineering came into being. It is interesting then to note that in 1907, when this plant was built, it was considered to be an outstanding example of up-to-date designs and was, in fact, one of the first plants in Eastern Canada to adopt the chain grate stoker. The plant, as then built, stood until 1912, when a fire occurred of such serious proportions that the whole plant had to be rebuilt, and it was 1914 before the plant was again in operation.

The new buildings were constructed of steel and concrete and brick, and when completed had a water frontage of 2000 feet on Halifax harbor. The refinery and power plant occupy a conspicuous position on the Dartmouth side of the harbor, and the tall chimney of the power plant rising 285 feet above the waters of the harbor, is an outstanding feature of the landscape.

The Power Plant.

The plant consists of a battery of ten Babcock & Wilcox boilers of 324 rated horse power, one of 430 horse power, and one of 640 horse power. The ten 324 h.p. boilers are equipped with superheaters, while the two latter boilers are used for supplementing the low pressure steam lines, and are not furnished with superheaters. Steam is used for both superheaters. Steam is used for both power and manufacturing purposes, the prime movers being turbines direct connected to generators. A very complete installation of coal handling apparatus has been installed, but owing to the fact that the plant is being changed over very largely to oil fuel burning, this will be very little used in the future. For the same reason the ash conveying plant is of little use at present, and a skip hoist is used, as will be explained in the course of the article. The coal burning boilers are being used only for emergency purposes, the daily load being carried on the oil fired units. The manufacturing requirements call for all the exhaust steam from the turbines, and also from the two boilers already referred to. All the returns are collected and delivered to the feed water heater, and the water from this is passed through an economiser and raised through a considerable range of temperature before delivery to the boilers. The above gives a general idea of the layout of the plant, and we can now introduce the reader to the details which go to make up the complete plant and ensure its efficient operation.

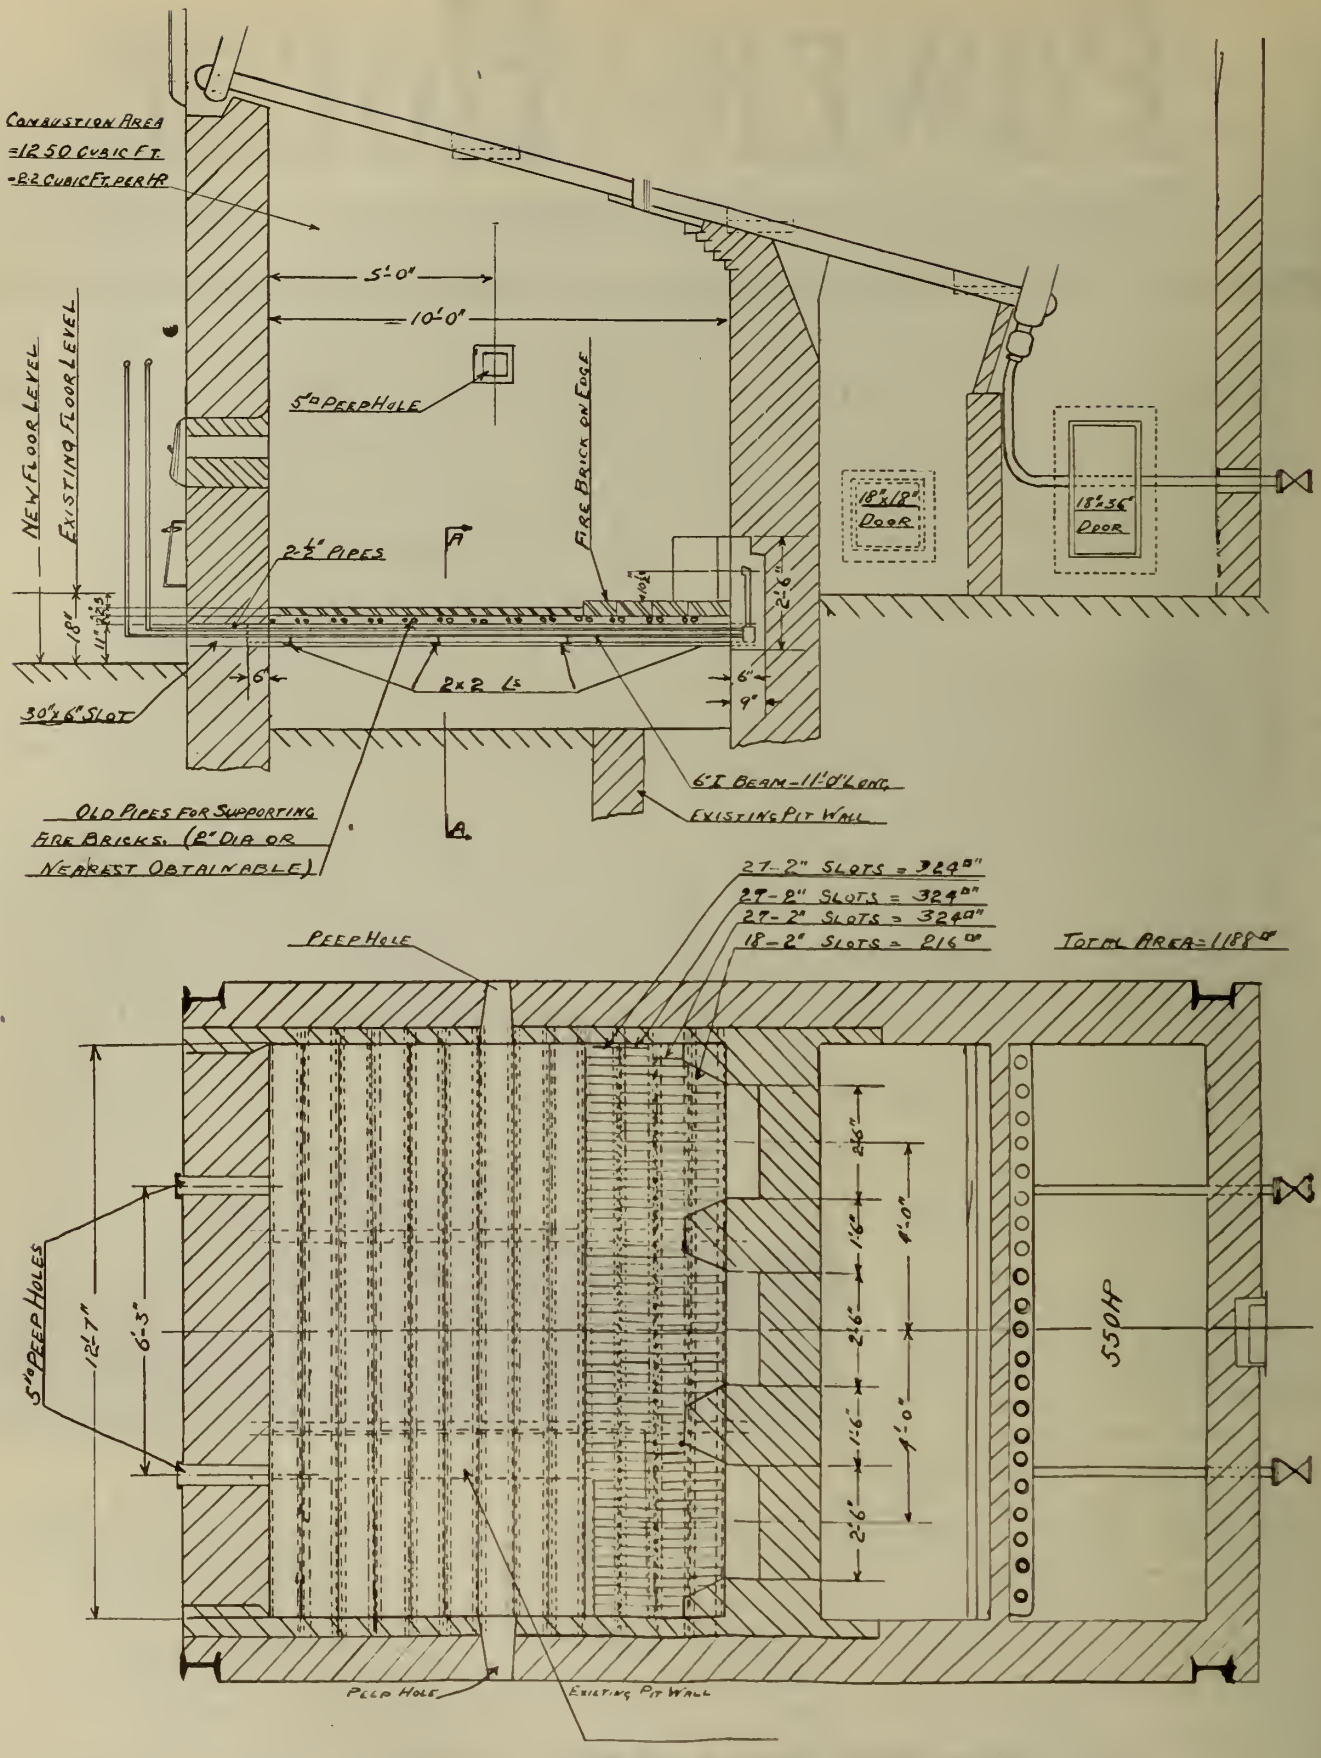


ACADIA SUGAR REFINERY

The Coal Handling Plant.

The coal handling plant is an interesting installation, having been designed with a view to complete control of the coal from the railroad cars or from barges, to the boilers, bunkers, or ground storage.

The complete conveying system has a capacity of twenty tons per hour, and is driven by one motor of 40 H.P., which is conveniently situated on the ground level, in a clean and accessible position. This motor drives to the main gear by a chain drive, while the various conveyors can be thrown in and out of gear by friction clutches. The motor, which is of the slip ring type, can be operated from the conveyor tunnel. Coal can be delivered to the overhead bunker which has a capacity of 450 tons, or to the storage, and it can be reclaimed from storage as required and delivered to the bunker. The storage has a capacity of 5000 tons, and the overhead bunker can hold 450 tons. There is a coal crusher of the two-roll type, 20 x 24 in., to break the coal up in small enough size for the chain grate, while the two main belt conveyors are 30 ins. wide with a capacity of 20 tons per hour, the smaller belts being



PLAN AND ELEVATION OF NEW SETTING

18 in. wide. The illustration, figure 1, gives a very clear idea of the layout of this conveyor system. On account of the elimination of ashes, the conveyor is not shown. The present arrangement is to take the ashes from the ash tunnel by a skip hoist, and dumped into a concrete storage bunker, from where it is loaded into railroad cars, etc., for use in grading, ballasting, and kindred uses.

The Boiler Installation.

The boilers that were served by this coal handling equipment, and which are partially served by it at present, are all of the Babcock & Wilcox water tube

type. The main battery consists of ten boilers, each having a normal rating of 324 H.P., which is obtained by the use of 32,400 square feet of heating surface.

A pleasing feature of the installation is the absence of the usual noise attendant on oil burning systems. This is mostly due to the remoteness of the atomizers. The change from coal to oil was made without having to modify the old settings to any great extent, and as the ashpits were unnecessary with the oilburning equipment it was an easy matter to lower the settings and shove the rear wall back without having to disturb the baffles.

There is also a superheater on each boiler, containing 8100 square feet which is in the ratio of one quarter square foot of superheater surface to one square foot of heating surface. The steam is superheated 125 degrees at the superheater, and enters the turbine stop valve at about 100 degrees superheat, the boiler pressure being 160 lbs. gauge. On account of the large amount of steam required for boiling and other manufacturing purposes, it is necessary to have two boilers in addition to the ten just mentioned, without superheaters. These boilers supply the steam lines in the factory with low pressure steam, but they can be used to supply the turbines if necessary. The heating surface of these two boilers is 10,900 square feet. All these ratings are of course capable of being raised if necessary.

The boilers are fed with water from the company's own reservoir, which has a capacity of 7,000,000 gallons, and is supplied from a lake situated about two miles from the plant. The water is pumped into the reservoir by two motor driven automatically controlled centrifugal pumps with a capacity of 1,000,000 gallons each per day.

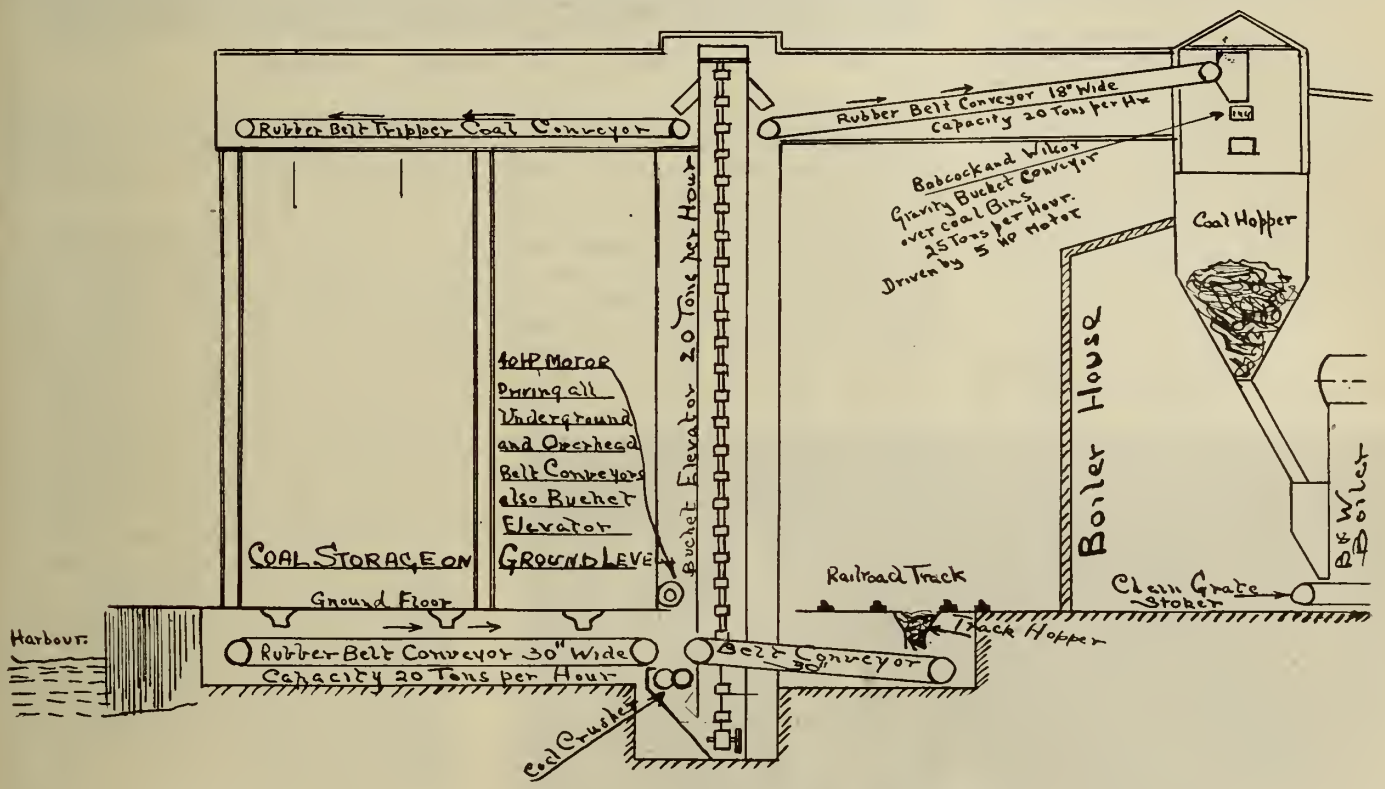
All the steam used in the building and in the turbines is returned to the receiver above the feed pumps. No feed heater is used, the temperature of the returns being in the neighborhood of 180 degrees and the pumps deliver the water to the boilers through an economiser containing 17,958 square feet of heating surface, which raises the temperature of the water entering the boiler to 245 degrees. This economiser reduces the temperature of the escaping gases to between 350 and 400 degrees. The feed water passes through a Venturi meter on its way to the boilers, so that a check can be kept on the quantity evaporated.

The feed pumps are of the centrifugal type, and consist of two Mather and Platts, motor driven, with a capacity of 250 Imp. gallons per minute at 414 feet head, and two Lee Courtneys turbine driven by Terry turbines of the same capacity. These pumps draw directly from the hot water receiver, which is placed about nine feet above the pump suction. Each boiler is equipped with a Crane non-return stop valve on the main steam pipe, leading to the header. The header itself is anchored in the centre and is free to expand towards either end. For manufacturing purposes steam is reduced through Locke regulators, and low pressure steam is also taken from the turbines by bleeders. For the purpose of obtaining accurate records of performance, steam flow meters and CO_2 recorders are being installed this year. The CO_2 outfit will probably consist of a recorder, with individual indicators on the oil burning boilers. Automatic feed water regulation is another feature to be installed during the present year. Natural draught is used exclusively, and for this purpose the stack is 255 feet above the level of the grates, with an effective area of 74½ square feet, making it capable of handling 4000 H.P. boilers. This is ample for the plant, which normally has about 3600 boiler horse power in service.

Oil Fuel.

The coal burning boilers are at present used as a standby—of these there are four.

The fuel oil is supplied by the Imperial Oil Company through a 4-inch underground line from their plant about 1¼ miles away. The oil is delivered to two receiving tanks shown in Fig. 4. These tanks are 35 ft. in diameter by 20 ft. high and have a capacity of 143,724 gallons of oil each. From the supply tanks situated at the rear of the plant and at an elevation of 40 ft. above the boiler room level the oil flows into two underground concrete supply tanks, with a capacity of 300 barrels of oil, or equivalent to about 100 tons of coal, bunker storage. The oil is pumped from the underground tanks through a steam heater at a pressure of 40 lbs. per sq. in. to the atomizers. The oil temperature is maintained at 190 deg. F. and the pressure is kept constant by a Locke regulator. The six 324 H.P. are equipped with two burners and the two larger boilers with three burners. The oil line to the burners is ½ in. diameter. The



SECTIONAL ELEVATION OF COAL CARRIERS

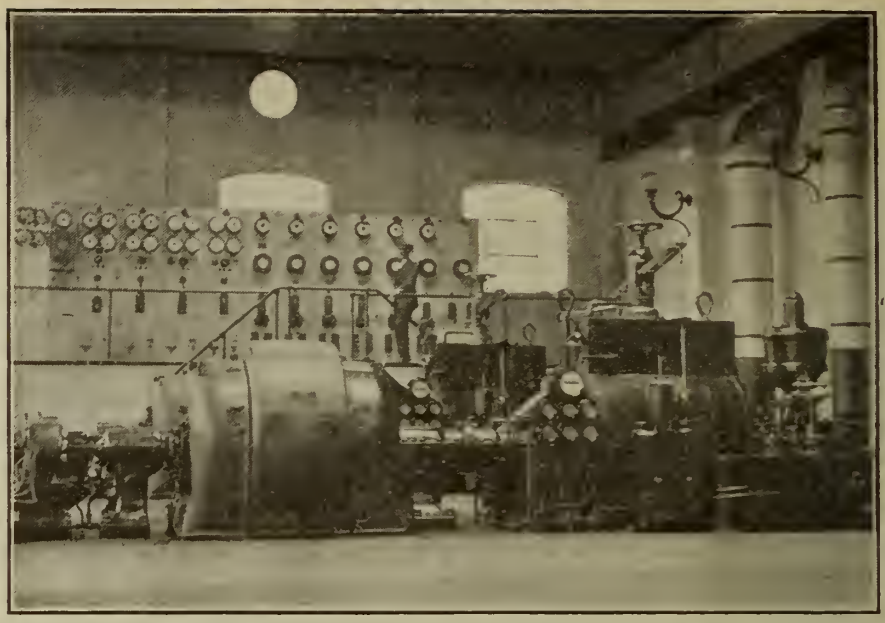
atomizers are of the Best and Leahey type, and are situated at the rear of the furnace.

In order to get the necessary furnace volume the settings were lowered 18 in. below the old floor line. This gave a furnace volume of 2.2 cu. ft. per H.P., and is in substantial agreement with good practice and makes for high combustion efficiency. As the burners are situated at the rear of the furnace the flame is projected forward and upward. This gives the gases of combustion an increasing volume away from the ignition point which feature has been proven to be highly desirable.

The distance from the centre line of the atomizer to the top of the checker work is 10½ inches.. The refractory material is laid on supports made from old 2½ in. pipe laid on beams. The checker work is laid for a distance of 3 feet toward the front of the setting and extends the full width of the furnace. The openings in the checker work are 2 x 6 in. and give an area of approximately 2.2 sq. in. per H.P. or approximately 1 sq. in. of opening per cu. ft. of furnace volume. With natural draft this works out very satisfactorily. The volume of air is controlled by dampers in the uptake. The oil to the atomizer is controlled by an operating valve at the front of the boilers.

Turbines.

The two main turbines are Westinghouse, non-condensing bleeder type—750 K.W. 3600 R.P.M. when exhausting at 23 lbs. abs. back pressure, into the low pressure heating line and bleeding 45,000 lbs. per hour from the first stage at 45 lbs. gauge pressure for manufacturing purposes. The steam pressure at the turbine throttle is 150 lbs. 100 deg. superheat (the writer recently saw the turbine in the foreground opened up for inspection and after being in operation for seven years the blading is still in good condition). The turbines are direct connected to Westinghouse 3-phase 600 V. 60 Cycle, 940 K.V.A. Generators, 3600 R.P.M. with direct connected 115-V.—80 A. Exciters.



MAIN TURBO GENERATOR AND BOARD

There is a 50 K.W. Standby lighting set, connected to a high speed Vertical Comp. Robb Armstrong Engine, size 9 x 14 x 7 in. stroke, 450 R.P.M. This 50 K.W. Generator can be put in on a peak load with any of the other machines or used for lighting at week ends.

The switch board consists of 4 Generator panels, 6 Feeder Panels and one Lighting Panel, and one synchronizing and Voltage Regulator Panel. The feeder circuits are protected by maximum current cutouts. The voltage regulator is one of the most important pieces of apparatus in the station, as the load swings are at times fully 60% of the station load and of frequent occurrence. The watt hour meters are at the rear of the board and there is ample room to work with a maximum of safety, there being 5 ft. in the clear. Under the switchboard gallery are situated the main oil switches and outgoing feeders. All electrical equipment is situated above the main floor. The basement being reserved for steam lines, generator air ducts, etc., the outgoing feeders pass from the power house to the main part of the plant through concrete tunnels. The switch board is made of white marble supplied by the Westinghouse Electric Co., and has a beautiful appearance, adding greatly to the brightness of the turbine room, which is done in white tile brick, 5 ft. high, the walls from there up are concrete with a coat of whiting. There is one 15-ton crane overhead for lifting purposes.

There are over 200 motors in continuous service in the main plant varying in capacity from 5 H.P. to 185 H.P. The conditions under which some of these motors are required to work is very severe, due to high local temperatures, and in some cases sugar deposits in the

VIEW OF OIL FIRED BOILERS

windings, thus closing the ventilating spaces almost entirely in a short time, which makes for short life of a motor. Every conceivable means is used to prevent this but without complete success, as once the deposit forms it cannot be blown from the windings like ordinary dry dust. It sticks in the crevices in a moist syrupy state and collects any dust that may be entrained in the ventilating air. Notwithstanding this handicap it is greatly to the credit of the Chief Electrician, Mr. Joseph Fawcett, that the plant has a well kept appearance, and is in continuous operation. Mr. Fawcett is only a young man, but has held the position of Chief Electrician for a number of years. All the electrical repairs are done under his direction on the plant, and he has an electrical testing laboratory, outfitted by himself.

Shipping Facilities.

The Company own their own lighter, and besides maintain a ferry service on the Harbor to accommodate their workmen. They have an extensive shipping wharf on the water front. Their shipping rooms and warehouses are equipped with the most modern labor saving devices for moving freight and piling.

Management.

The management of the plant is under Mr. F. A. Bodenheim, who before coming to Canada was connected with the largest Sugar Refineries of the Southern States.

Mr. John S. Misener, a Halifax boy, is assistant manager and chief engineer. Mr. Misener when a boy served his time as a mechanic in Halifax and made rapid progress in the Engineering profession, having been active in quite a few new installations and while yet a very young man, made good. He has been connected with the Acadia Sugar Refining Company for the past 14 years and has had the carrying out of various engineering improvements which attracted considerable attention from the engineering profession in Canada.

Engineers who are sufficiently interested in oil burning will be well repaid by a visit to this plant, if they can afford the time.

The writer wishes to express his appreciation of the courtesy of the Management in placing at his disposal blue prints and other data in connection with the plant.

Other Pumps.

For general service purposes through the power plant and refinery, there are fitted two Rees Ro-turbo pumps, each having a capacity of 5000 gallons per minute against 140 feet head. For fire protection there is a 1500 gallon Allis-Chalmers underwriter type pump, and a complete Grinell sprinkler system, dry pipe.

REGINA'S NEW TURBO GENERATOR

A 5,000 kw. turbo-generator has recently been installed in the city of Regina's No. 2 plant, commencing operation on November 9, 1920 The unit is a General Electric Curtis five stage 3,600 r.p.m. of latest design having a maximum rating of 6,250 kilowatts at unity power-factor.

The turbine is designed for 200 lbs. pressure gauge and 100 degrees F. superheat and a vacuum of 28 in. referred to 30 in. barometer and on test with lower steam pressure of 180 lbs. gauge and vacuum ½ in. away from barometer the steam consumption has proven as shown on Fig. No. 1. This shows that at 4,000 kw. load the steam consumption is 52,600 lbs. per hour or 13.15 lbs. per kilowatt hour. The consumptions at 2,000 and 1,000 kw. are also shown which are consistent and point to a no-load steam consumption of just under 6,000 lbs. per hour.

The turbine exhausts into a 7,450 sq. ft. Westinghouse condenser fitted with Leblanc air pump and condensate pump all direct connected to and driven by 40 h.p. motor at 700 r.p.m. This condenser receives its circulating water from a central circulating plant consisting of two 24 in. 12,500 gallons per min. Mather and Platt vertical shaft centrifugal pumps running at 265 r.p.m. and one 14 in. 5,000 gallons per min. Gywn horizontal centrifugal pump running at 430 r.p.m. These pumps are all direct connected to and driven by motors. The large pumps are driven by 110 h.p., G. E. motors, and the 14 in. pump by 40 h.p. Westinghouse motor.

Operating conditions are favorable and with circulating water at prevailing temperature of 40 degrees (in winter) a vacuum within ½ in. of barometer is regularly maintained with the small circulating pump operating alone.

The turbo-generator is an A T B, 6,250 kv.a., 3,600 r.p.m., 2,300 volt, and is fitted with temperature coils for indicating the hottest temperature points of generator.

The generator is connected to regular switchboard in plant (which is arranged for six generators and feeders with duplicate bus bars) through duplicate oil circuit breakers fitted with overload and reverse power relays.

Exciting current is from regular exciters of plant which are controlled by Tirrill voltage regulators.

The five-stage Curtis turbine consists of five wheels, the first wheel having a blade pitch diameter of 35 inches and the remaining four wheels having a blade pitch diameter of 51 inches, the length of blades increasing from a length of ⅞ inch on second wheel to a length of 9⅛ inches on last wheel.

Shaft glands are steam pocked, the leakage from high pressure end gland being tapped off from a point where pressure is above atmospheric pressure and led to low pressure gland by a large pipe passing through the turbine exhaust chamber. An unloading valve is fitted by which any excess steam from high pressure gland (other than the amount needed for the low pressure gland) is passed to the last two stages of machine.

The governing is done by progressive opening and closing steam valves admitting steam at full boiler pressure to more or less nozzles which act on the double row wheel of first stage. The valves are controlled by a cam shaft which receives its motion from an hydraulic plunger operated by the regular oil pressure of machine which is maintained at 70 lbs.

Oil pressure for machine is maintained by the regular gear type oil pump, direct driven by worm from turbine spindle or by a small turbine driven gear pump which is of the vertical shaft type, the whole auxiliary being a complete unit and hangs from top of oil reservoir with the gear pump submerged.

The generator has a direct connected exciter, but in the machine installed only overhung collector rings were provided. The field of the generator is solid, the winding being in radial slots with non-magnetic metal retaining wedges.

The shield packing where the shaft passes through the end bells of the generator is especially designed to prevent the suction of fans carrying oil vapors into generator. This packing is of a modified labyrinth type and air from the discharge side of generator fans is led down to the centre of this packing, this making a flow of air outward; or, in other words, this gland is air-packed. The bearing ends are also fitted with a similar connection and are supplied with air from generator fans to prevent oil vapors being forced out of bearings along shaft where it is difficult to handle and usually is drawn into any revolving parts of machine such as collector rings. With this arrangement fitted to bearings air is actually forced into bearing shells from the ends and is taken care of by a liberal vent pipe.

The coal consumption per kilowatt hour that may be obtained from a machine of this type, operating on a load curve as shown on graphic wattmeters, and in connection with a modern boiler plant, is shown by plant records for October, November and December of 1919, when the original machine carried all of plant load. The records show a coal consumption as follows:

October average load on machine, 35.1 per cent.—coal per kw. hour, 1.97.

November average loan on machine, 39.6 per cent.—coal per kw. hour, 2.07.

December average load on machine, 41.6 per cent.—coal per kw. hour, 2.03.

The coal consumed was Western bituminous of about 12,400 B.t.u. per pound for October and a mixture of Western bituminous and Saskatchewan lignite of approximately 11,000 B.t.u. per pound for November and December.

*Electrical News.

Overhauling and Adjusting in the Engine Room

In This Article the Steam End of the Ordinary Duplex Pump Is Described. The Steam Valve and Gear are gone into In Detail.

By "FITTER"

HAVING in the previous articles gone into the water end of the pump fairly explicitly, we will now take up the steam end, which is where a good many engineers slip up until they have acquired the requisite experience. The steam piston is a simple enough proposition, but the arrangement of the steam valve is different in practically every make of pump, and we shall illustrate a few of the principal makes and explain their design. Especially in the case of simplex pumps where the valve is worked from the pump rod is difficulty experienced, but when the principal on which these valves work is understood we are sure that there will be no trouble in keeping a pump working.

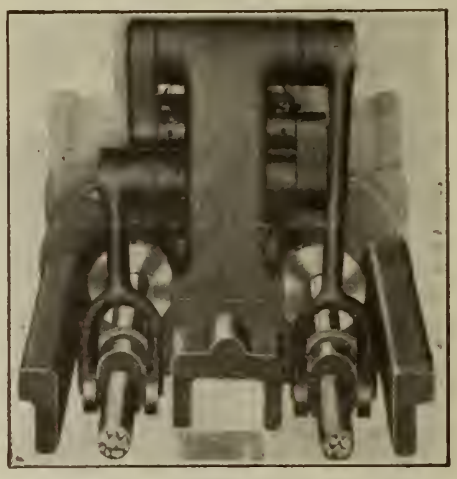
The Steam Piston.

The steam piston is almost invariably of the plain type, cast solid, with grooves turned in the circumferences for the reception of cast iron spring rings, or what are commonly known as Ramsbottom rings. The only trouble encountered with these pistons is that due to wear, and the remedy of course is boring out and the fitting of new rings, or sometimes a complete new piston and rings. The cylinder is usually counterbored for the easier introduction of the rings, and the piston is secured on the rod by two nuts and a cotterpin or taper pin. The rod is of course tapered for the reception of the piston in the usual manner. In larger pumps the piston is sometimes built up with a junk ring to carry the spring rings and a follower plate, and the rings themselves are sometimes made sectional. However, there is nothing in the piston itself to occasion any difficulty in the overhauling or running of the pump, the construction being self-evident when the pump is opened up for examination.

The mechanism for distributing steam to the pistons is, as we have said, of a very different order. There being no eccentric to give motion to the valve, except of course in the flywheel type of pump, a valve which is more or less self actuating has to be employed. Probably the most simple type of a steam valve gear is that employed on the ordinary duplex pump, in which the gear is so arranged that the pump rod on one side works the slide valve on the opposite side. The valves are of the simple slide type, with an exhaust cavity in the center. The flywheel type of pump has a slide valve exactly similar to any other steam engine with the addition in many cases of a Meyer cut-off valve. The simplex type of pumps are invariably fitted with a double type of valve, in which the movement of a small auxiliary valve by the pump rod furnishes a steam to throw over the main steam valve from side to side, and thus open the main steam ports to the cylinder at either end alternately. With this type of valve sometimes a very small alteration in adjustment will suffice to stop the pump, or make it work in a very erratic fashion, and it is therefore necessary for the successful engineer to have a clear understanding of the principles involved in their design.

Duplex Valve Pump Valve Gear.

In the usual type of duplex pump the valves are worked from levers operated by a spool and lever arm from the pump rod. The gear consists of a bracket which is bolted to a saddle cast on the frame of the pump between the steam and water ends, this bracket containing



ARRANGEMENT OF VALVE GEAR

two bearings in which the rocking shafts of the valve arms work. These bearings are offset in order to give working clearance, and are set one above the other. The lever arm which is driven by the pump rod is keyed on to one end of the rocking shaft, and the valve arm on the other, so that the lever on the right hand pump rod operates the steam valve on the left hand cylinder. The levers are of different lengths, that connected to the top rocking shaft being of course longer than that connected to the bottom. A short connecting rod connects the valve spindle with the pin on the valve arm, and the spindles are screwed at the end which enters the valve to take the adjusting nuts.

Owing to the position of the rocker shafts in the brackets, the valve arms are keyed on to the shafts in opposite positions to each other. That is the valve arm on the top rocker shaft looks downward, while that on the lower shaft looks upwards. This brings the valve arm pins in line with each other, and with the valve chest. It also has the correct effect for driving the valves, as we can see with a little study. Supposing the right hand cylinder is the one with the long lever, then the left hand valve will be driven from the top rocker shaft, and the valve will move in the same direction as the right hand piston. Now when the right hand piston goes forward the left hand valve will also go forward, and give steam to the left hand piston to drive it forward. When the left hand piston goes forward, however, its lever will drive the lower rocker shaft, and as the lever valve arm is keyed to this shaft looking upwards, it will move the right hand valve in the opposite direction to the left hand piston, thus giving steam to the right hand piston for the return stroke. It must be understood that in this type of valve gear the valve spindle nuts are given clearance from the valves, so that it is only when the respective pistons are nearing the end of their stroke that the valves are operated. The effect is to give quick opening to steam, and a full port opening while the piston is making its stroke. In the accompanying sectional illustration of a duplex steam valve the arrangement can be seen plainly, while the outside views gives the arrangement of the levers.

The steam cylinder has two ports at each end with the exhaust port in the middle, as is the usual practice. It will be noticed, however, that while the cylinder is double ported the valve is only single ported. The object of the two ports in the cylinder is to give a cushioning effect at the end of the stroke, and it is accomplished as follows:

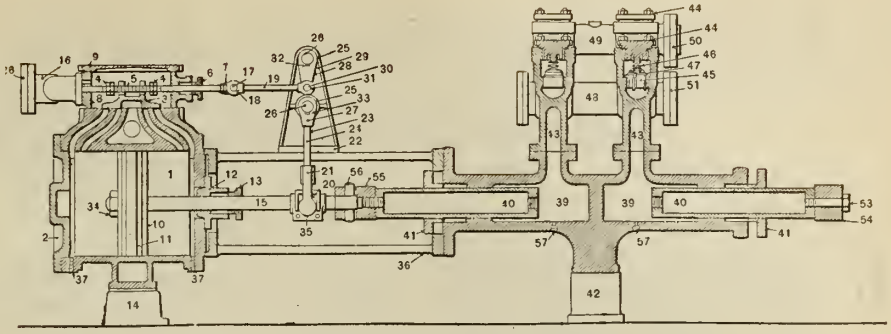
It will be noticed that the outside ports, that is, those at the extreme ends of the cylinders, lead into what is practically the clearance space. When the piston is approaching the end of its stroke it will completely cover the inside port, thus leaving only the end for the exhaust to escape from, and as the valve does not come back far enough to completely uncover this port, the restricted area has the effect of holding back the steam and building up the pressure to bring the piston to a stop gently. At the commencement of the stroke, this restricted port opening has the opposite effect, that is, it just gives steam enough to start the piston off

gently, and when the inner port is uncovered the full steam opening is obtained, after the piston has got well under way. This tends to smooth running, and absence of sudden pulsations.

Looking at the sectional view, it will be seen that the valve lever and valve arm that are shown are directly vertical, while the valve is in its mid position. In this position it just covers the steam ports or in some cases it leaves them barely cracked. The nuts on the spindle are a little way clear of the valve, and it will be seen that the distance they allow the valve to move in just sufficient to uncover the port at either end, depending on which way the valve is moved. This gives the key to setting these valves.

If the spool on the pump rod is in its correct place, and in pumps where this spool is held by a tapered pin, there is little chance of it moving, then when both levers are absolutely vertical, the valves should be placed so that they are just covering the steam ports, and the nuts adjusted so that the valves can move exactly equal distances on each side of the center line. If the spools are not secured by a taper pin but by a set screw, and they should happen to have been misplaced, then the piston should be set in the middle of its stroke, and the spool placed on the rod directly under the lever as it hangs vertically downwards. The center of the stroke can be found by moving to the poston each end of the cylinder alternately, and marking the rod at each end, and then dividing the distance between the marks.

The action of the valves is as follows: Suppose both pistons and valves are in mid-stroke. Both valves will be closed to steam, and the pump will not start from that position without outside help. If the pump has been in service for some considerable time, and the gear has a lot of lost motion, it will be still harder. However, the pump must be moved by a bar from its central position, that is one side must be moved. The pump here illustrated has the left hand pump rod driving the top rocker shaft, and that means that the right hand valve is operated by the valve arm that hangs down. Supposing now we take a bar and move the left hand pump rod forward. The right hand valve will be moved forward from its middle position, and the back steam ports will be opened to steam, the right hand piston starting to move to the forward end of the cylinder. The left hand valve will not move until the right hand piston has moved forward enough to take up the slack in the valve spindle nuts, and then as the right hand piston is operating the rocking shaft on which the valve lever is keyed looking upwards, the left hand valve will be moved backwards. This will open the ports on the forward end of the left hand clyinder to steam and thus the left hand piston will move backwards.



SECTION VIEW OF DUPLEX PUMP SHOWING VALVE

Now look at the right hand valve again. When we moved the left hand rod forward to give the pump a start, we had to move it sufficiently to bring the back valve spindle nut up to the valve, which means that all the slack is now on the frontside of the valve, and the valve will be open to steam on the back and exhaust at the front. As the piston moves forward it will cover the inside port, and slow down in its movement gradually as it comes to the end of the stroke. The left hand piston meanwhile will have been travelling back to the outside end of the cylinder, or back end if you like, and moving the top rocker shaft until the front nut on the right hand spindle comes up against the valve, and moves it backwards. This opens the front ports to steam on the right hand side, and the back end to exhaust, so that the right hand piston starts its return stroke, and in doing so moves the left hand valve forward to give the left hand piston steam and start it on its return stroke. It can readily be seen that if a great deal of slack is allowed to get in the various pins and bushings that make up the motion, a very unsatisfactory result will be obtained from the valves. In the duplex pump it is important to look closely after the oiling of the shafts and pins of the valve gear, and so prevent undue wear. The motion is so slight that many engineers seem to think that oiling is superfluous, while in other cases there is lots of oil all round and over the pump, but none in the places where it should be, owing to the small oil holes being blocked up. The slide valves should have a little lubrication till they get a good face, likewise the pistons, but after the pump is well bedded down, there is no use smothering it with cylinder oil which is expensive. The moist steam which is supplied to these pumps in most cases acts as a very efficient lubricator, and oil should be used just as judgment dictates, by the result of the periodical examination. There should be a regular time to examine the steam ends of pumps the same as any other apparatus. Unfortunately, too often pumps get stuck in dark dirty holes and corners where they wear their lives away in about one-quarter the time they should, purely from neglect.

When the bushings or pins of the valve gear get worn it is a very easy matter to have the bushings reamed out and new bushings fitted or spare parts secured from the makers. However, it is pretty safe to say that the average life of these parts could be doubled if proper attention was paid to their lubrication and cleanliness.

In subsequent articles we will take up the valve gears of various simplex pumps, this being a subject which we know from experience will be very welcome to many engineers.

TORONTO NO. 1 LODGE C. A. S. E.

Toronto Lodge No. 1, C. A. S. E., held a very successful meeting on Wednesday, June 8th, the occasion being the installation of officers for the ensuing year. The following officers who had been duly elected were formally installed in office:

Past President, Brother G. D. Bly; President, Brother S. G. Hall; Vice-President, G. Bones; Recording Secretary, R. G. Edwards; Assistant Secretary, W. T. Green; Financial Secretary, R. C. Leach; Treasurer, A. M. Wickens; Conductor, J. J. Wilson; Door Keeper, Ed. Golightly.

In addition to the installation of officers, two new members of the Lodge were initiated. It was announced during the evening that a lecture, illustrated with lantern slides, would be given on June 22nd, at 8 p. m., the subject being "Green's Economiser," the slides having been kindly loaned by Mr. Wellington, the local agent of the firm. Mr. Fenner, editor of Power House, will deliver the lecture.

CATALOGUES.

Messrs. Greene, Tweed & Co., 109 Duane street, New York, have issued a circular describing their "Poplar" packing, which has been designed for moderate steam and hydraulic pressures, that is below 100 lbs. per square inch. Low temperatures are also necessary where this packing is employed, and the packing has been designed for service where a moderate priced material can be used successfully. The packing is saturated with the firm's graphite grease compound, and then plaited solid.

A Course of Instruction for the Graded Certificate

A few more examples of indicator cards showing defects in the steam distribution are explained. Single cards only have been dealt with so far.

By T. H. FENNER

FOLLOWING up the interesting subject of indicator diagrams, we shall take up a few of the different varieties of defects shown on the cards. These defects do not always arise from the valve, but sometimes are due to the indicator itself, though these latter defects are usually very easily seen and corrected.

SHOWING EFFECT OF LEAKY VALVE

If you get a card which has a steam line looking like a perspective view of the Alps, don't jump to the conclusion that there is something radically wrong with the engine. Such a card is shown in Figure 1, and it is usually an indication of a tight or dry piston in the indicator, which causes a jerky motion of the spring. Taking an indicator diagram with too light a spring will also cause some funny effects, everything being greatly exaggerated. Make sure before taking a card at all that the cocks are clear or else you may easily get a card that has such a small area you will wonder what is going on, and how the engine carries the load. Too heavy a spring will make the card so small that you will not be able to distinguish anything from it. I think it has been mentioned in an earlier lesson about the drum of the indicator being free the whole stroke of the engine, that is, that the indicator drum does not come up against its stops before the engine reaches the end of its stroke. If this happens you will get an absolutely straight steam admission line, which doesn't happen in actual practice.

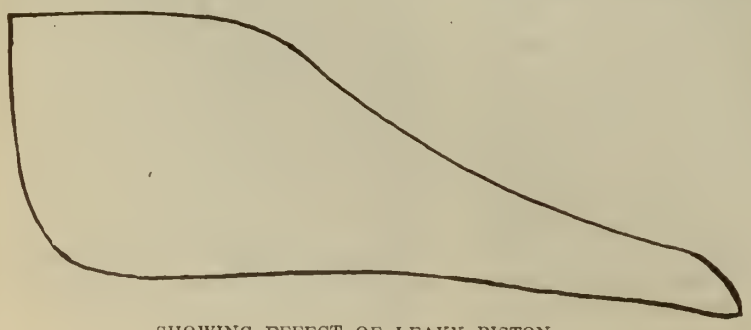
Supposing you have a valve that is not tight, that is, after cut off has taken place steam is still leaking through to the piston. The effect will be an expansion line with a hump on it, as shown in the illustration, while it is quite probable that the same effect will be shown on the back pressure line. The hump on the back pressure line may be caused by a leaky piston, allowing the steam to leak from the high pressure to the exhaust side of the piston, and raising the back pressure.

Drop valve gear engines invariably show a better card than slide valve engines, owing to the quicker closing of the valve when cut off takes place. This has the effect of making the corners sharper, thus improving the expansion curve. The illustration given shows what a card from a Corliss engine in good condition should be like. With the Corliss gear the quick opening of the valve also gives a very straight steam line, and any quick opening gear will do this as well as the true Corliss type. With the slide or piston valve one sees a sloping steam line. If this slope should be exaggerated it is due to the steam port not being wide enough for the engine, or the steam pipe leading to the steam chest not being large enough. Throttling produces the same effect. With a compound engine it is usually due to the receiver on the low pressure cylinder not having large enough capacity, or too early a cut off in the H. P. cylinder.

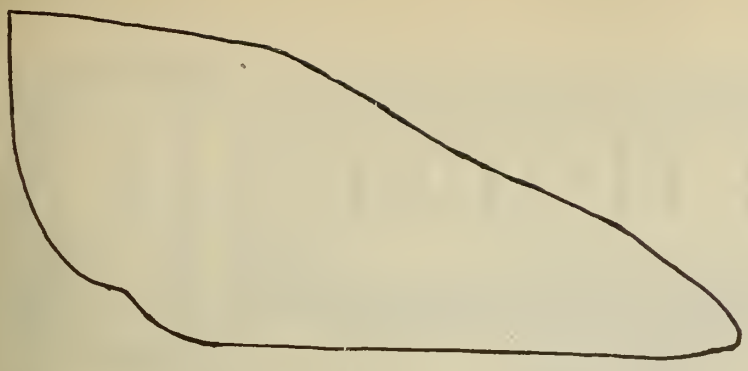
A loop at the top or steam line of a card is usually due to excessive compression, which causes the back pressure to raise above the initial pressure before the piston reaches the end of the stroke, and when the valve opens to lead the pressure drops to the initial pressure. Excessive lead will cause the admission line to rise above the initial pressure, but in this case it does not cause a loop, but merely a sort of peak at the corner of the card, as shown in the example in last issue.

GOOD EXAMPLE OF CORLISS ENGINE CARD
NOTE STRAIGHT STEAM LINE

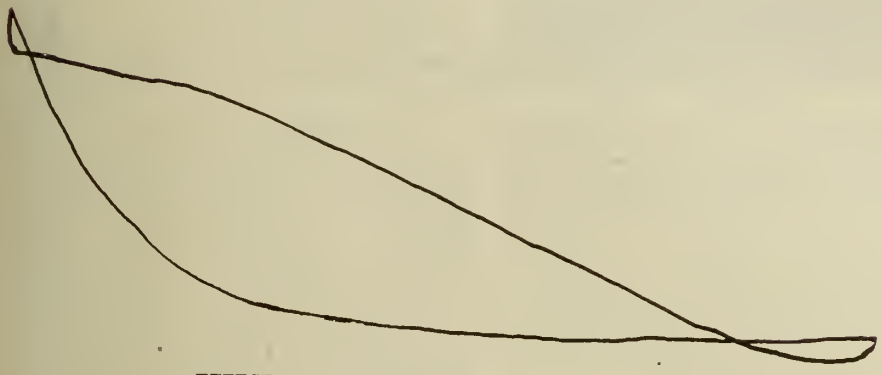
A case sometimes noticed is where there is a hump in the compression line, as shown in the illustration. This is caused by the top and bottom exhaust ports being open at the same time. This condition is sometimes found in high speed engines where there is minus exhaust lap, that is, the inside edge of the valve does not cover the ports when in mid-position, but leaves them just a little open. It thus happens that before the valve closes to effect compression, the exhaust port from the other side of the piston is momentarily open, and as the terminal pressure on the stroke is somewhat higher than the back pressure the higher pressure steam passes down to the other side of the piston. This causes a momentary rise of pressure, but the valve almost immediately closes and the compression curve starts. This



SHOWING EFFECT OF LEAKY PISTON

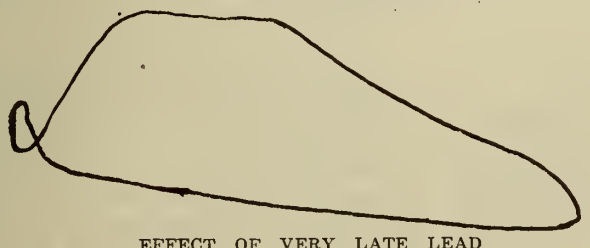


SHOWING EFFECT OF MINUS EXHAUST LAP



EFFECT OF THROTTLING

SHOWING HIGH COMPRESSION



EFFECT OF VERY LATE LEAD

is not often run across but there are examples, and several writers refer to them. Another example is where the loop occurs in the compression line. This is due to very late lead, so that when the piston is at the end of its stroke the steam which has been compressed starts to expand before the valve opens to admission. This results in the loop being formed as shown.

Sometimes a loop will be formed at each end of the card, at the top and bottom. This is due to early exhaust opening which allows the terminal pressure to fall below the back pressure while the compression curve beginning very early runs the back pressure up above the initial pressure.

Generally speaking, any deformity on a card can be traced to the source that caused it by close examination. The defects given above are those most usually run across. We have so far only spoken about cards from one end of the cylinder, but we will now take up the case where the cards are taken from both ends on the one card, and show how to correct them when defective.

BIG INCREASE IN POWER COSTS

How These Charges Have Been Increased During the Last Few Years

Cost of power occupied the time of Paul M. Lincoln, the noted American electrical engineer, in his address to the Electrical Engineering Institute at the Physics Building of the University of Toronto.

Mr. Lincoln dealt largely with fixed charges and operation ratio of electrical plants throughout North America. He showed that the price of every raw material had increased tremendously since before the war, and that this made an enormous difference in the price of operation of electrical plants then and now.

A Steady Increase

The actual operation cost dropped from 1910 to 1914, the average drop running about 5 per cent., but since 1915 there has been a rapid and steady increase in power house costs.

Mr. Lincoln estimated that the cost of a power plant to-day would run to 225 per cent. more than it did in pre-war times. This means that the public must pay, in the same ratio, these increased charges.

In plants which are operated by coal power, Mr. Lincoln showed that the coal costs during the past few years had considerably enhanced the cost of power. Further, he stated that the cost of labor in operation of power plants might be taken at 85 per cent. in excess of what it was in 1914. In total, he fixed the ratio of expenses in power operation from 1914 to 1920 as approximately 2½ to 1.

At the last meeting of the Montreal section of the Engineering Institute of Canada, an address was given by G. E. Newill, the general manager of the Robb Engineering Works, of Amherst, N.S., on the development of turbine construction, and in particular, on the achievement of the Dominion Bridge Co., of Lachine, in building a turbine power installation for the British-American Nickel Co. at Sudbury. It will be interesting to know that this is the first time that an engineering firm in Canada has accepted the challenge to construct a large power turbine of this character, running as it did into about a quarter of a million dollars and requiring all the precision of mechanical discernment and nicety that might be needed in the making of a full jeweled watch to be propelled by steam.

An Irritating Practice

A CONDITION has arisen in some power plants which is causing a good deal of indignation among the operating engineers, and not without reason. This is the practice adopted among some managers and factory superintendents of having the steamfitter's crew perform alterations to steam piping and valves in the engine and boiler room without consultation or reference in any manner to the man who is responsible for the general upkeep and good condition of the plant. An instance is given where a steamfitter in repairing a blow-down pipe, substituted a smaller piece of pipe for the one he had taken out, in spite of the protests of the engineer in charge. The steamfitter's argument was that the smaller pipe would do just as well, and that he was not under the engineer's orders, anyway.

This condition is a very unfair one for the engineer in charge. The Government compels him to pass an examination and take out a license to show his competence to take charge. They will hold him responsible for any accident that may take place, and on the other hand the management holds him responsible for the economical and safe working of the plant in his charge. The steamfitter or plumber may be a very good tradesman, without having any particular knowledge of the principles involved in steam engineering operation. Any repairs or alterations on that plant should be done under the engineer's supervision, or else he should be relieved of any responsibility for what is done. This alternative is something he does not want, as it nullifies his position, and relegates him to a position which he has been steadily climbing out of. Repairs in the factory, where the engineer is not in charge of the whole of the machinery, may properly be done under the direct supervision of the foreman steamfitter, or where there is only one steamfitter employed, under the direction of the manager or factory superintendent. In the power plant itself the chief engineer should be the only one to say how and what should be done. If he is not competent to handle this work, he is not competent to handle the plant. Strictly speaking, where there is a force of steamfitters and plumbers employed in a factory, they should be under the direction of the chief engineer or the plant engineer if there be such an official. Where there is, and the power plant engineer is under the direction of the plant engineer, any work done in the engine and boiler room should be done under the direct supervision of the power engineer, for it is he who has to operate it, and be responsible for it.

Factory managers cannot expect to get the best out of their power plant if the operating head is subjected to petty annoyances of this nature. They would not send a junior clerk from the shipping department to make entries in the books of the cost department over the head of the cost accountant, and the power plant engineer is entitled to at least the same consideration.

Modern Boiler Settings.

THERE seems to be a good deal of doubt among some operating engineers as to the height of boiler settings, or rather, the height the boiler should be set above the grate bars. Time was, and not so very long ago, that a horizontal return tube boiler was set with the shell some 24 to 30 inches above the bars, the idea being to get the benefit of the heat. This notion, which was fundamentally wrong, has now been completely discredited, and boilers are set from four to five feet high, that is, H. R. T. boilers. Water tube boilers with horizontal tubes are set as high as twelve feet above the bars, it being a well recognized fact that there must be plenty of room for the gases of combustion to become ignited before they meet the comparatively cool surfaces of the tubes or shell of the boiler. The example of the candle and the piece of glass is as good as any for showing the correctness of this practice. If a piece of glass is held closely over the flame of a candle, close enough for the flame to touch the glass, it immediately becomes smoky. That is, a deposit of soot is formed on it which insulates it from the heat. If it is held further away from the flame there is no deposit, but the glass becomes heated much more rapidly. The same thing happens with the shell or tubes of a boiler. If set too close to the grate, the flame strikes them, and the gases are cooled off before they get a chance to complete combustion, and the surfaces become quickly covered with a carbon deposit. Good modern practice is to make the combustion space above the fire grate equal to the cube of the grate width. That is, with a grate, say 25 square feet, the boiler would be set five feet above the grate bars.

This is, of course, subject to modification, but is a fairly good approximate rule.

Build in Canada.—The English Electric Co. has announced its intention of extending operations to Canada, and it is understood that they will erect factories in Toronto for the manufacture of electrical machinery and equipment. The company, which is said to be the largest firm of its kind in the British Empire, and one of the most powerful industrial enterprises in the world, includes among its directorate Sir John Mansell, Lord Meston and representatives of John Brown & Co., Cammell, Laird & Co., Thomas Firth & Sons, and Harland and Wolff. M. Gordon F. Perry, president of the National Iron Corporation, Toronto, has been appointed chairman of the Canadian board.

We have received from Messrs. Dayton Dowd, Quincy, Ill., their bulletin No. 244 describing their line of centrifugal pumps, for all purposes.

Progress in New Equipment

BOILER FEEDING BY GRAVITATION

WE recently had an opportunity of investigating a new system of feeding steam boilers, which is being introduced by the firm of Royles, Limited, Irlam, near Manchester. The apparatus has been in use at the firm's own works for about three years, where it has given the utmost satisfaction, being both simple and reliable. In fact, there is an almost entire absence of moving parts. The system has been appropriately named "the Auto-thermal Feed." For its operation the apparatus depends upon gravitation, and it possesses the advantage that it can deal with water of high temperature, and can, therefore, make use over again of the water which has been evaporated, together with the water from a feed heater or from steam traps.

Fig. 1 shows the arrangement of the apparatus in conjunction with an overhead feed tank and exhaust steam feedwater heater applied to a Lancashire boiler. Fig. 2 is a sectional elevation of the two vessels forming the single lifting unit, which serve to collect and lift the water. Fig. 3 is an enlarged sectional view of the main steam valve which operates the lifter, and Fig. 4 is a similar section of a diaphragm valve the function of which will be described later.

The appliance consists of a lifter C, E—Figs. 1 and 2—and a feeder H—Fig. 1. The lifter receives all the water of condensation from steam traps, etc., together with the make up feed to the boiler, and lifts it into the feeder H, which is situated well above the boiler, whence the water gravitates into the boiler. The lifter consists of a receiving drum C with suitable tappings for the discharge pipes of steam traps, etc., one being allocated to the feed water heater shown on the right-hand side of Fig. 1, so that all the feed water is received into one common vessel. From the receiving drum all the water gravitates through the valve D, the opening of which can be adjusted, and the flap valve D^1—Fig. 2— to the lifter drum E, which is connected by means of the check valve G and a vertical pipe X to the feeder H, the pipe X also acting as a return pipe to convey the water from the feeder to the boiler through the valve K—Fig. 1.

The rise and fall of pressure in the lifter drum E, in performing its function, is utilised to admit steam from the boiler to the feeder at the proper time in the cycle of operations, and the perfect working of the apparatus is due largely to the manner in which this is done. The synchronisation of the two operations is of the utmost importance to perfect working. The steam and exhaust valve F—Figs. 1 and 3—has been specially designed for the purpose. It consists of an inlet valve L operated by a piston M. The spindle of this valve carries the exhaust valve N, the two valves being arranged that the movement of opening the steam inlet closes the exhaust outlet and vice versa. The steam, after passing through the valve F, is delivered into the lifter drum E through the perforated pipe shown in Fig. 2. A small hole O in the piston M of the valve F—Fig. 3—allows a certain quantity of steam to pass the piston and to put it into equilibrium. P is a poppet valve for exhausting the steam from the underside of the piston M under the action of the two tappet arms U and U^1—shown in Figs. 1 and 2—which in turn are operated by the float Z in the chamber E rising and falling as the lifter fills and empties. A pipe W connects the inside of the lifter with the underside of the diaphragm Q in the valve J—Fig. 4—the plunger of which, through the spindle V, opens and closes the double-beat valve R, S, T, which alternatively admits live steam to the feeder H or exhausts the latter under the rise and fall of pressure within the lifter. The supply of steam to the feeder must be direct from the boiler, but the steam for the lifter need only be of sufficient pressure to ensure the water being lifted into the feeder.

Assuming that the apparatus has just delivered a supply of water to the boiler, the feeder H will be full of steam at boiler pressure, the valve S being open to the boiler and the valve T—Fig. 4—closing the exhaust. Similarly, the lifter cylinder E being empty the float will be at its lowest position, and the tappet lever U^1 will be pressing the poppet valve P against its seating—as shown in Fig. 2 the steam pressure being thereby retained under the piston M, which is then in equilibrium, while the valve L is held against its seat. The exhaust valve N, being open, water entering the collecting drum C is free to gravitate into the lifter E, raising the float and eventually opening the poppet valve by the tappet lever U, thus exhausting the steam from below the piston M. The area of the top side of that piston being greater than that of the lower side of the valve L, the steam pressure causes the piston to fall and open the valve L, thus admitting steam to the lifter E and closing the exhaust valve N. The pressure in the lifter is conveyed through the pipe W to the diaphragm Q in valve J—Figs. 1 and 4—which is forced upwards,

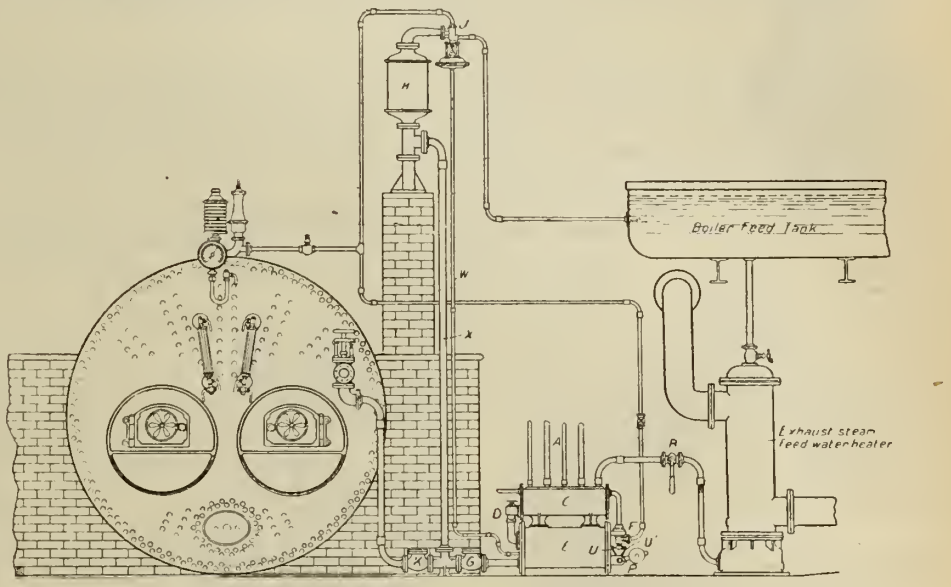

FIG. 1 GENERAL ARRANGEMENT

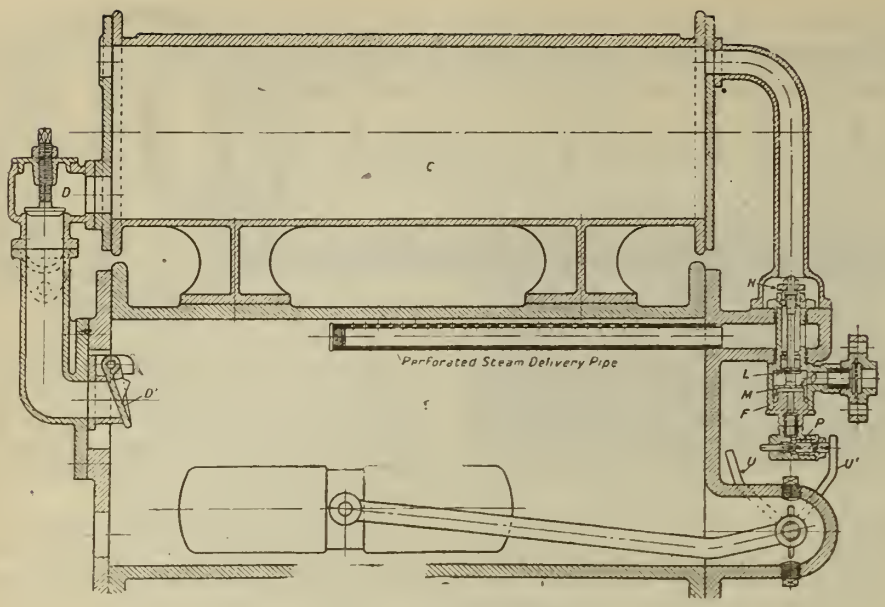

FIG. 2—LIFTING UNIT

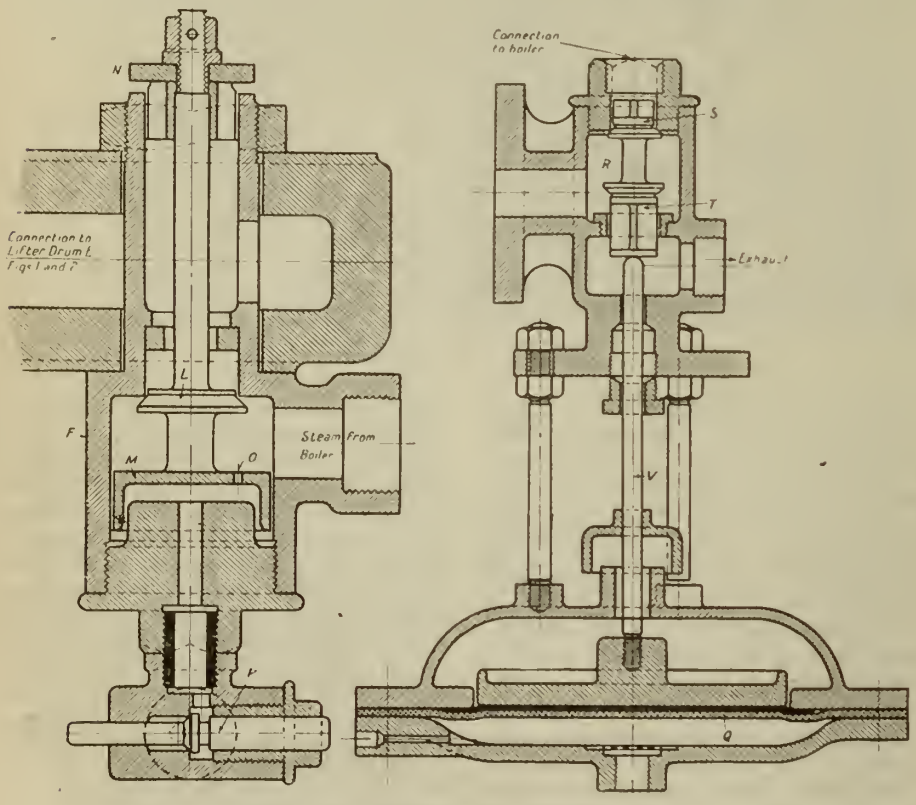
closing the steam inlet S from the boiler and opening the exhaust T, and as soon as the pressure in the feeder H has fallen sufficiently the water from the lifter ascends into the feeder through the pipe X. The float in the lifter then falls and closes the poppet valve P again. Steam pressure then accumulates under the piston M through the hole O and the valve L is closed again, thus shutting off the steam from the lifter drum E and opening the exhaust valve N. The fall of pressure in the lifter brings down the diaphragm Q in the valve J, closes the exhaust valve T, and allows steam at full boiler pressure to pass the valve S into the feeder H and drive the water into the boiler through the pipe X and the non-return valve K, thus completing the cycle.

The proper working of the appliance is largely due to the effective way in which the exhausting or admission of steam to the feeder H is controlled by the lifter E. A considerable amount of experimental work was necessary to perfect the main steam valve F—Fig. 3—and the valve motion has been so designed that it cannot stop in mid-travel. The valve L holds to its seat until the reduced pressure on the underside of the piston M causes the pressure on top of the piston to pull the valve L away from its seat.



FIGS. 3 & 4—SECTION OF VALVES

The apparatus is made in various sizes, from 250 gals. to 3,000 gals. per hour. That in use at the makers' works is of the 1,000 gals. size, and gives two strokes or pulsations per minute.

ERROR.

In the article on Low Pressure Heating Systems which appeared in the issue of May 20th, page 39, column 3, the formula for the area of a safety valve was incorrectly stated. The correct formula is

$$W = \frac{a\,(P+15)}{.22} \quad \text{and} \quad P = \frac{.22W}{a} - 15$$

ANNOUNCEMENTS

The Jos. W. Hays' Corporation have issued a folder describing their various appliances for effecting fuel economy. These include the well known CO2 recorder, draft gauges, gas analyser, boiler setting compound, etc. A postcard ready addressed to the corporation and bearing spaces for data on boiler plants is included, for those who wish to obtain further information on the articles included in the folder.

* * *

The Combustion Engineering Corporation have recently been compelled to increase their office space in the Philadelphia district, and also inaugurate a new service department. The new office is located on the 10th floor Finance Building, Philadelphia, and is under the management of Mr. W. C. Stripe.

* * *

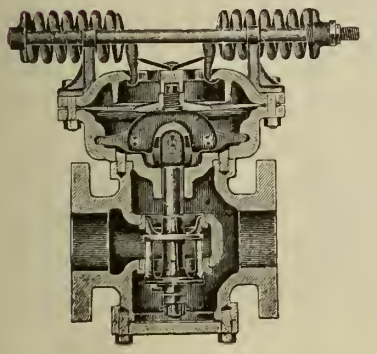
Jones & Glassco, Montreal and Toronto, announce that they have been appointed the sole agents in Canada for Steel Belting. This belting, while comparatively new in Canada, is largely used in Great Britain, for power transmission in industrial plants.

Formed New Connection.—D. J. Beatty, formerly advertising manager for the Northern Electric Co., has resigned to go into partnership with G. L. MacGillivray in the G. L. MacGillivray & Co., Ltd., 103 Notre Dame Street West, Montreal. This company was recently formed to look after the selling interests of the following firms in Eastern Canada: Edwards & Co., Inc., American Insulator Corporation, Waterbury Manufacturing Co., Chase Metal Works, Parker Supply Co., Inc., R. M. Radio Co. of London, Eng., the Prometheus Electric Co. For some time prior to enlisting for overseas service, Mr. Gordon MacGillivray was assistant supply sales manager for the Northern Electric Co. at Montreal.

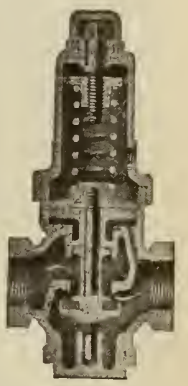
FOSTER

Pressure Regulating Valves

are giving continuous satisfaction



ENGINEERING skill and a broad, practical knowledge in the manufacture of valves have never been applied with better success than in the design of Foster Pressure Regulating Valves, of which there is a special type for each particular requirement.



Foster Pressure Regulators are simple in construction and their noiseless, friction-less operation insures long life. Other features are: Renewable seat rings, ample steam capacity, no small parts to clog, ease of adjustment, accessibility for repairs, small movement of diaphragm, parts of drop forged and case hardened steel, etc.

Foster Back Pressure Valves are also exceptionally high-grade and satisfy the most exacting requirements.

Our nearest Sales Office is prepared to fill rush orders and will gladly furnish any information you may require.

If it isn't there write us.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

SIMPLE OR COMPOUND HOISTING ENGINE

Question.—What is the difference between a simple hoisting engine and one with a second motion gear?

Answer.—An ordinary two-crank hoisting engine is composed of two cylinders of equal size mounted on each gear which is keyed to the hoisting drum. In the case of a second motion engine the engine is arranged so that it can drive through compound gears instead of direct. In this case the pinion on the crank shaft is mounted on a clutch, and when the engine is running in single gear the clutch is engaged with the pinion driving the gear as in the ordinary single engine. When the compound gear is used this clutch is disengaged and the pinion is allowed to run free on the shaft. A second pinion at the other end of the shaft also mounted on a clutch is put in gear with a spur wheel on a second motion shaft, and on the other end of this shaft opposite the main drum pinion there is a third pinion also furnished with a clutch. This clutch is engaged and drives the main drum spur gear.

MEANING OF CORROSION

Question.—What is meant by corrosion?

Answer.—General corrosion is the oxidization of metal under the action of air and water, and is a species of slow combustion. It can be prevented by careful attention to the surfaces in danger of corrosion, keeping them well painted with protective paints, such as red lead. Where the surfaces cannot be painted as in the heating surface of a boiler or any part of a boiler internally below the water line then the metal must be kept clean and free from deposits of any kind. This particularly applies to the form of corrosion known as pitting, where the oxidization is localized into small pits, which gradually spread. Electrolytic action is caused by electrical discharges between different metals in the presence of water, and can be prevented by introducing a material that will be more susceptible to the electric discharge than the metal of the boiler. This is usually done by hanging zinc plates in the water space, the hangers making good metallic contact with the stays, tubes or shell of the boiler.

BLOWING DOWN BOILERS

It seems strange that there should be a difference of opinion about the proper time to blow down a boiler, assuming of course that the object of blowing down is the removal of mud or scale forming matter.

We are told by some book writers, some boiler inspectors, and occasionally an engineering magazine that the proper time to blow down is when the fires are dead, and we are told as proof of the correctness of this theory to watch the process of emptying a bath tub, the idea being that the emptying of a bath tub is the analogy of blowing down a boiler. This is so to a certain extent and would be a perfectly satisfactory illustration to anyone who is able to make the proper deductions from the evidence it gives.

The proper time to blow down a boiler is when the fires are active, because then the mud is in suspension in the water and any percentage of water blown out carries the same percentage of mud. This does not include matter that is so light that it will float no matter how rapid the circulation may be. Only a surface blow-off will get such.

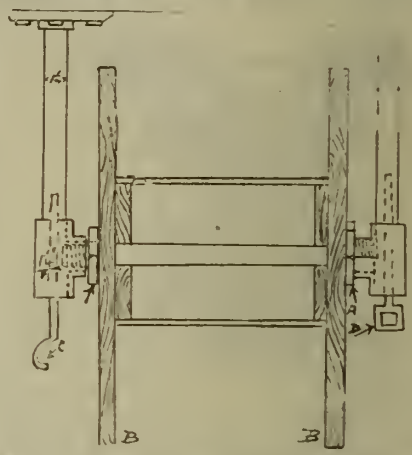
When the fires are dead circulation is dead and the mud finds a resting place on either the tubes or the shell and blowing down will not remove it.

This may be proved by any engineer who wishes to know the truth, if he will remove the top man hole plate before emptying the boiler for washing out. He will find the water clear and a deposit of mud on the tubes. When he opens the blow-off he will see the water lower without a particle of mud being moved until the water begins to uncover the tubes. Then the mud will be carried off the upper row of tubes. When the water begins to uncover the next row the same thing occurs, and so on at each successive row. When the water level gets down near the bottom the velocity of flow from the front of the boiler toward the rear becomes rapid enough to carry the mud deposited there along with it.

It is this stage of emptying a boiler that is illustrated by the emptying of a bath tub.—R. McLaren.

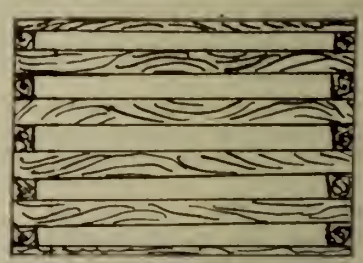
MAKING A HOSE REEL

The hose reel illustrated here will compare favorably with many more expensive types, and is easy to build and very substantial. A piece of 1-inch iron



PLAN VIEW OF REEL FASTENER TO WALL

pipe is used for an axle, and two strips of round wood with pieces nailed on around them form the drum. The 1-inch pipe is held in the drum by locknuts "A." The sides can be made of wood, or round pieces nailed to the drum as at "B." The brackets consist of two flanges, two 1¼-inch tees, and two



MAKE UP OF DRUM

pieces of 1¼-inch pipe. The reel can be attached either to the wall or ceiling. A hose wrench and hydrant key are shown at "C" and "D."

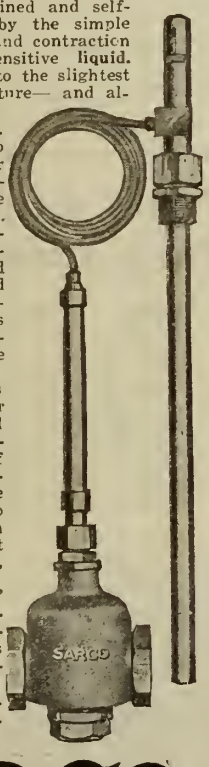
Secure United States Work.—In competition with eight other elevator companies, the Fegles Construction Co., the only Canadian firm tendering, received the contract for the construction of an eighteen hundred thousand bushel elevator in Brooklyn, N.Y. The elevator will be known as the Barge Canal Terminals at Gowanus Bay, Borough of Brooklyn, the contract being $1,500,000. The terminals are to consist of fifty-four concrete tanks, a boiler house and power house, together with installation of machinery, the whole to be completed in every detail and ready for occupation by September 1, 1922.

Why Gauge Temperature By Guess?

THE man trying to watch and control temperature may keep it right four times out of five—perhaps nine times out of ten—but sooner or later he is sure to slip up—and every time he does a batch of expensive material is either spoiled or damaged.

Why depend on mere guessing—on hit or miss uncertainty, when you can have absolute certainty?

A single batch of spoiled material, a single process gone wrong through the uncertainty of guessing, will frequently amount to several times the cost of a Sarco Temperature Regulator—an automatic heat control that absolutely guaranteed to be accurate and dependable under all conditions.



Entirely self contained and self-operating—operated by the simple and sure expansion and contraction of an extremely sensitive liquid. Instantly responsive to the slightest variation in temperature— and always positive and certain in its action. No electricity, no compressed air or water, no outside attachments or outside aid of any character.

Because of its simplicity, its elimination of complicated attachments and other involved mechanism, it costs less than any other regulator—and is more easily installed.

Operates on gas steam or hot water heat. Can be supplied to control temperature in any kind of manufacturing process — including the most delicate. Also for control of room temperature, hot water temperature, etc.

Sold on 30 days' free trial—if not satisfactory simply return it and it costs you nothing whatever.

For further information write for Booklet No. J-52.

PLANT WILL HAVE GREATER CAPACITY

Changes Being Made To Give Larger Output for Electrical Apparatus.

Owing to the substantial development that has taken place in the electrical equipment business of the Canadian General Electric, it has been found necessary to take over some of the space that has formerly been included in the Allis-Chalmers plant.

This will be utilized after the necessary equipment has been secured, some of which will be taken from other plants, for the making of transformers.

Mr. J. J. Ashworth, general manager of the Canadian General Electric, intimated that it would take some time to finish making the change, but that when completed the plant would be capable of much greater production of electrical equipment.

The plans of the company also call for the disposal of a large amount of used machinery, part of which was used in their war contracts.

Rumors that were prevalent some months ago regarding a large match factory that was to be built in Canada by British manufacturers seem now to be on the point of consummation, as it is stated that Sir Alexander Maguire, of the firm of Maguire, Patterson and Palmer, will shortly come to Montreal to negotiate for the erection of the necessary factories in this district.

* * *

BRANTFORD FIRM TAKES NEW LINE

Darling Valves Will be Made at Plant of the Dominion Steel Products in Short Time.

BRANTFORD. — Announcement was made of the taking over by the Dominion Steel Products Co. of the Darling Valve and Manufacturing Co. of Williamsport, Pa. This company makes a line of valves for waterworks, oil lines and other pipes and hydrants, and has a reputation very high in Canada as well as in the United States, where the parent plant is located. Owing to the high duty on their products, which in the United States sell for a higher price than the products of their competitors, the market in Canada was limited, yet despite this they were used considerably, Brantford and Ottawa being among the cities which utilized their goods.

It was reported at the D. S. P. that the company was already receiving business in the new lines. The signing of the contract means that No. 1 and No. 2 plants will be opened for the manufacture of these goods as soon as necessary changes can be made, particularly in the foundry. It will take three or four weeks to bring these changes into effect and to get the plant upon a full production basis.

NOVEL USE FOR TRACTORS.

A sudden strike among the employees at the electricity station in a British town interrupted the supply of current to the local factories and thus brought them to a standstill. Help came, however, from an unexpected quarter. One of the factories was engaged on the mass production of tractors for agricultural and other purposes; and within a few hours a number of tractors were employed to supply the necessary power in this factory. Twelve tractors were belted up to a shaft from which several motors were driven as dynamos, this novel installation giving an average output of two hundred horse-power. Other tractors were used to drive machines directly. When the news of this got about, demands for the tractors came from other factories, and the emergency service so provided greatly discounted the effect of the strike.

ELECTRIC SOLDERING IRON

The use of the electric soldering iron to manufacturers in general is too self-evident to require any comment, and a new type of such an iron has been offered to the trade by the Vimy Supply Co., 567 College St., Toronto, Ont.

This iron has been approved by the H.E.P.C. and Power House has had an opportunity of handling one. It is very compact, has a push button control in the handle, and the copper bits are readily removed and new or larger bits inserted if required. This is accomplished by means of a suitable socket. The iron heats up very quickly, and the control button in handle regulates the heat. One button is painted red. By pushing this in the circuit is made through the element. With every iron is given a guarantee for one year, also a few hints to iron users in general that are well worth following out.

POINTS FOR TWIST DRILL USERS

If the drill chips on the edge it indicates that the lip clearance is too great and fails to support the cutting edge. This may be because the drill is too hard. It is advisable to ease off on the feed and watch the grinding.

If it splits in the web, it is either ground with improper centre lip angle or the feed is altogether too heavy. The centre lip should be at about 45 degrees to the cutting lips of the drill. The drill is in best condition when the chip comes out in a close coil.

If the outer corners wear it shows that the speed is too high and it should be reduced. This is particularly noticeable in drilling cast iron.

Drilling cast iron can be done at a little faster speed than for steel, but the corners must be watched.

LIGHTING PLANT FOR SALE—1200 UNit Lalley light farm-lighting plant; new; complete with Willard storage batteries, 32 volt; suitable for summer home; lighting at half price; for immediate cash sale, $400. Apply, mentioning Power House, Smith & McLaughlin, 259 Colborne St., Brantford, Ont.

SITUATIONS WANTED—MALE

STATIONARY ENGINEER (2ND CLASS)—would appreciate steady position in country; references A1. Apply, mentioning Power House, to Box 218, Globe.

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House.

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers. Corliss and all classes of stationary engines, compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St., Toronto.

ONE FIRST-CLASS SAWMILL MILLwright wanted at once. Apply, giving references and wages wanted to Box 613, Globe, mentioning Power House.

EMPLOYMENT DESIRED

POSITION WANTED BY AN EXPERIENCED refrigerator engineer, also competent in ice making and electricity. Address, D. M. J., Power House, Toronto. (p1h)204

What is said to be the largest single cylinder steam engine in Europe has recently been erected at a German steel works. The engine is of the Uniflow type, has a normal rating of 4,000 horse power, and is used to drive a three high 30-inch steel mill. The engine has a maximum rating of 8,000 H.P. The cylinder is 68 inches diameter with a stroke of 56 inches, the speed being 136 revolutions per minute and the working pressure 130 lbs. The weight of the crank shaft is 30 tons and the flywheel 90 tons. The main bearings are 29 x 48 ins. long and are water cooled.

Consideration will be given in the designs for the proposed power plant at Morwell, near Melbourne, Australia, to recovering the by-products from the fuel that would be required for raising steam. In that case the boilers would have gas fires. If it is considered preferable to burn raw coal, an experiment will be made of feeding it in the pulverized form to the furnaces. Another experiment will be made with feeding small coal and dust to a forced draught travelling grate stoker. The Commissioners have made arrangements for putting down an experimental briquetting plant at a cost of about £30,000, which will briquette 70 tons a day. The ultimate capacity of the power station, it is proposed, will be 100,000 kilowatts.

If you want something unusual

and it isn't advertised here, the logical thing would be to advertise for it. Double I Beam

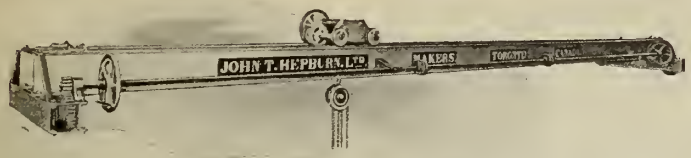
Send Us a Plan of Your Shop



HEPBURN HAND OVERHEAD CRANES

are built with single or double I-Beams, in a range of sizes from 1-4 ton to 20-ton capacity. The Hepburn Trade-Mark is your guarantee of strength, efficiency and long service. Also a full line of Pumps, Vertical Engines, Compressors, Iron Castings, etc.

Send us a plan of your shop, stating the width, the height, the load to be lifted, and the headroom available, and we will show you how a crane which will save you money, could be installed. It won't cost you a cent to get this information, and we urge that you make a survey of your shop at once. The result may reveal many possibilities that will surprise you.

John T. Hepburn Limited
Engineers and Iron Founders
18-60 Van Horne St., TORONTO

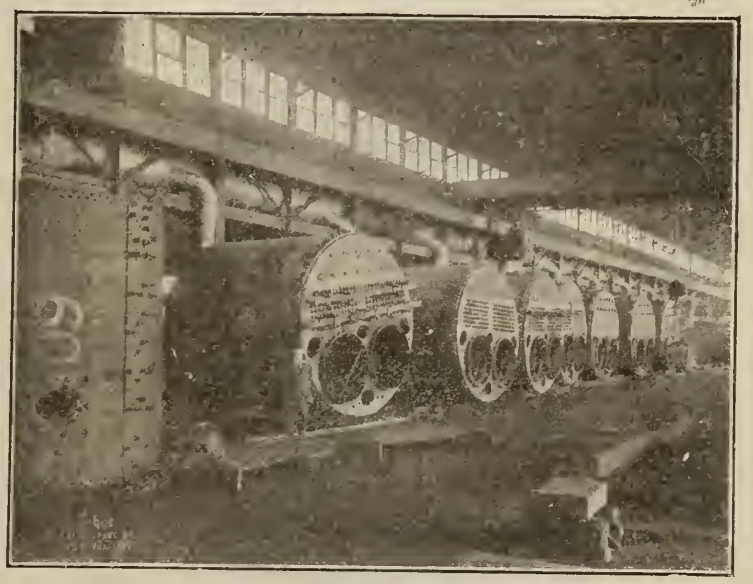
Steam — Steam — Steam!

¶ No business can do without it—either in a literal or a figurative sense.

¶ The shop that doesn't improve or renew its Boiler equipment now is losing a valuable opportunity — our service is at its best and new, low prices are available.

¶ We make every type of Boiler, steel plate work, castings, etc.

¶ Write us to-day.



Our Boiler Shop—"going strong"

Engineering and Machine Works of Canada, Limited

HALL MACHINERY CO., Sherbrooke, Que., and Birks Bldg., Montreal

What's in a Name?

In buying NEW and USED Power Plant Equipment it is much to your advantage to say

PETRIE

Quality--Service--Satisfaction; that is what we guarantee on

Tanks—any size, any capacity up to 2,450 gals.
Vertical Boilers—1 to 75 H. P.
Horizontal Boilers—6 to 200 H. P.
Firebox Boilers—12 H. P.
Marine—Internal Fired.
Automatic Engines—15 to 450 H.P.
Vertical Engines—7 to 75 H. P.
Horizontal Engines—5 to 40 H. P.
Write for full particulars.

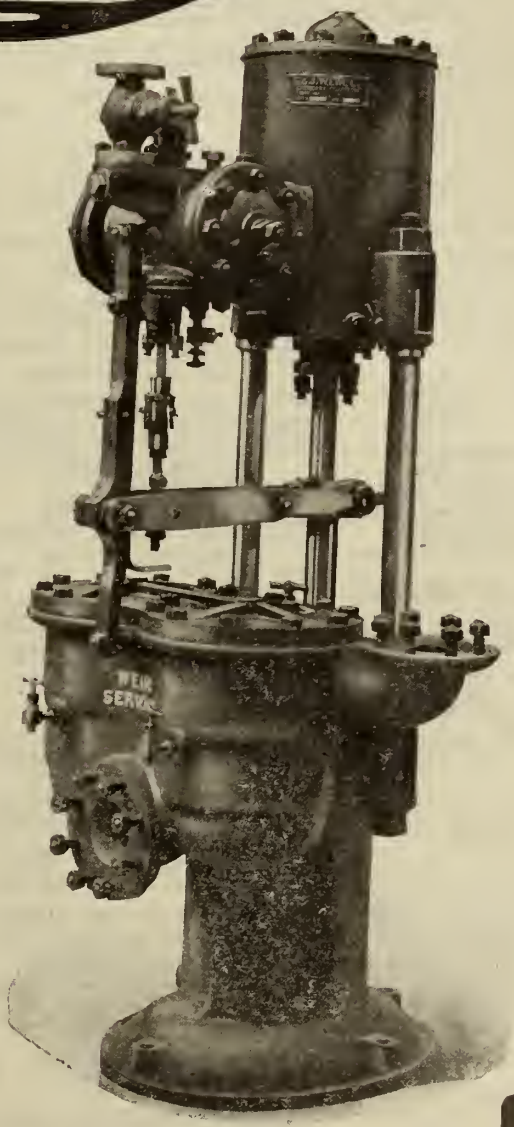
General Service Pumps
Direct Contact Heaters
Multiflow Heaters
Evaporators and Distillers.

PRESTIGE

The steady, confidence-inspiring service of 65,000 Weir Pumps, all over the world, is daily maintaining the international prestige of all products marked "Weir."

Watch a Weir Pump at work. Its slow, even, powerful strokes will convince you that it is accurately designed and properly made for long, efficient service.

In addition to Weir standard pumps there are a large variety of designs for special duties. For high duty installations, for water or oil, we can supply special patterns, simple, compound or triple, for pumping against pressures up to 1,000 pounds per square inch.



Special attention is paid to the prompt dispatch of goods and the routing and shipment of all consignments. Special instructions in this regard always receive our most careful attention.

Prompt and careful shipment is but a single phase of Weir Service. To serve our customers in every way to the best of our ability is our aim.

Made in Canada

WASTE ---
The ROBBER

Fuel waste is robbing your power plant of thousands of dollars.

Only by stopping all the leaks in your power plant can you stop this loss.

By installing the ELESCO SUPERHEATER you protect your power plant from one costly leak in your coal pile.

The ELESCO SUPERHEATER is an investment in any size plant, the returns from which begin just as soon as it is in operation.

Behind the ELESCO SUPERHEATER is the reputation of an organization which has made superheating a worth-while investment in many thousands of boiler horsepower successfully operating in all parts of the world. Such an investment and such protection warrant your early decision in favor of the ELESCO.

ELESCO

The Superheater Company, Ltd.

Transportation Building, MONTREAL
Works at SHERBROOKE, Que.

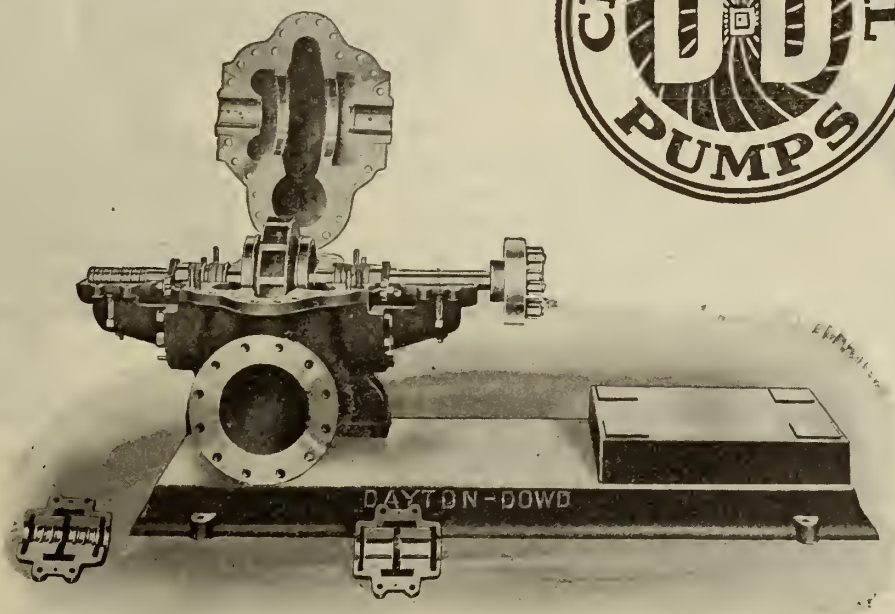
Dayton-Dowd

CENTRIFUGAL DD PUMPS



Type C S Single Stage Double Suction Centrifugal Pump

Showing Upper Half of Casing Raised—Note Ease of Access to all the Working Parts.

Because of its many advantages over other pumps, the centrifugal type is receiving the preference in the majority of installations. Dayton-Dowd centrifugals embody the most advanced principles of design; they represent the most modern high-grade standardized centrifugal pump possible to produce.

The C S pumps are of the non-overloading type, and so designed that power consumed under any conditions of variation of head will not exceed the power required under normal operation. This feature protects the Motor from overload.

The single stage C S centrifulgals are furnished with impellers of the enclosed, double-suction type. The design and finish of the impeller determines in a large measure whether the pump will meet its specified conditions. Years of experience in centrifugal pump designing and comprehensive tests enable the Dayton-Dowd Engineering Department to design the impellers and acquire the maximum efficiency possible for any specified duty.

The features of this pump are many in number—bulletin 240 explains them; send for it.

McGowan Duplex

STEAM AND POWER DRIVEN
DURABLE PUMPING EFFICIENT
MACHINERY
PISTON AND PLUNGER TYPE

EST.—1852

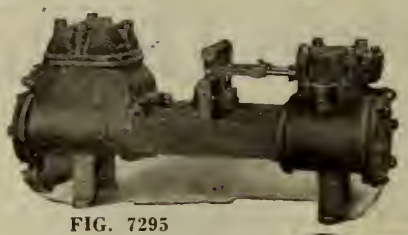

FIG. 7295
Packed Piston Boiler Feed Pump.

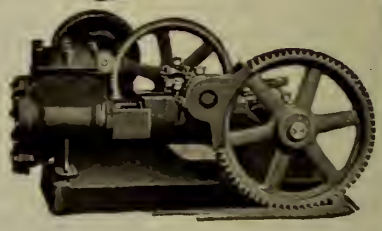

FIG. 7404
Made in piston and outside center packed plunger pumps for both top and side motor mounting.

UNIFORM SPECIFICATIONS of a high standard govern the production of all McGowan Duplex Steam and Power Driven Pumps, which are built on the interchangeable system of parts, under the same rigid inspection inaugurated in our works by the United States Shipping Board Emergency Fleet Corporation, in connection with the production of pumps for the Emergency Fleet.

THE STEAM DRIVEN PUMPS are built in both piston and plunger types for all commercial purposes up to capacities of 3,500 gallons per minute, while the Power Driven Pumps are built in both piston and plunger types for all commercial uses up to capacities of 500 gallons per minute.

DIRECT SALES. The late improvements adopted in our Standard Duplex Steam and Power Driven Pumps require a revision of our bulletins, which work is now under way; pending the time they are available for distribution, our sales must of necessity be handled direct by the Home Office. The lowest price, consistent with the high quality of material and workmanship represented in the pumps, will be quoted.

FIG. 7439
Packed Piston General Service Pump

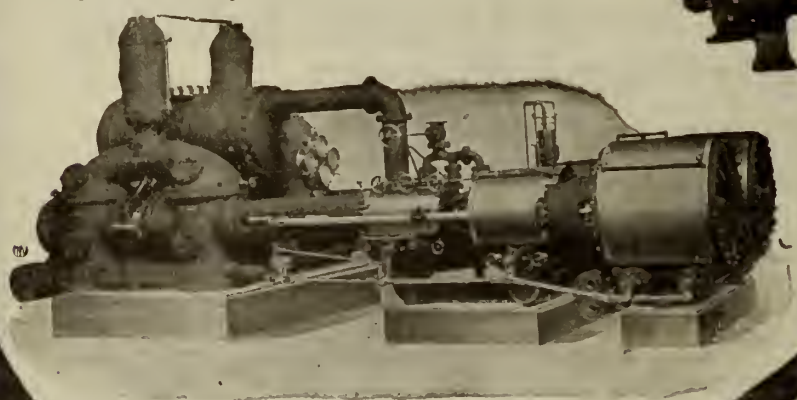

FIG. 7362
Water Works Pumping Engines; Capacities up to 5,000,000 Gallons per Day.

Adaptability of Laclede-Christy Stokers

Adaptability in any stoker equipment means that it can be applied to any type of boiler, from the small return tubular to the huge, present-day water-tube units of 2500 H. P. and over. Adaptability also means the ability to burn any sort of fuel, through the long series from lignite to coke braise. That Laclede-Christy Stokers completely satisfy these demands is evidenced by the above list of typical installations.

THE L-C CHAINGRATE STOKER—the *Natural-Draft* type for higher volatile coals—dominant in its field today.

Branch Offices: Chicago, 1366 Peoples Gas Bldg.
New York, 504, 50 East 42nd St.—Pittsburgh, 901 Oliver Bldg.

THE STOWE STOKER—for *Mechanical* Draft. "The stoker that doesn't make fuel problems—it solves them."

Morrison Pressure Recording Gauges

"Of course, you have a high opinion of your ability as a fireman.

"Can you convince the 'boss' that you are the best man he could get for the job?

"This Morrison Pressure Recording Gauge is just the thing to do your convincing. It takes a continuous record of your steam pressure—thus showing exactly that you have kept it up to the mark every hour of the day. Don't you think you *need* this proof of your ability?"

Fireman—"I sure do!"

(*two days later*)

Fireman: "Here you go 'boss,' this is the chart of our steam pressure for the last twenty-four hours as shown by that pressure recording gauge I got you to install yesterday. Don't you think it proves my ability to keep a constant steam pressure?"

"Boss": "It looks that way. But, how do you know the gauge is correct?"

Fireman: "Why, because it's a Morrison product."

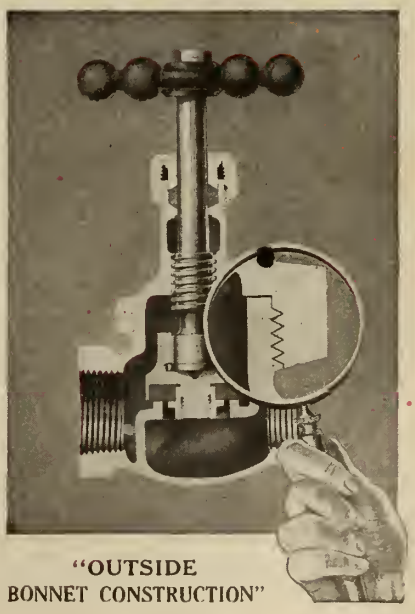
TRADE PENBERTHY MARK.

A SAFE GUIDE IN VALVE BUYING

"Be Sure This Name is On the Valve You Buy"

In the illustration to the right we have marked with the circle the one big improvement in our valves over other makes, viz: "THE OUTSIDE BONNET CONSTRUCTION." The bonnet *does not* screw *into* the body of the valve. It fastens to it by *Outside* threads on the body, which threads never come in contact with the corrosive action of the steam and water. They are *away* from it. The result is, the valve bonnet and body can always be taken apart without strain or injury. This construction also prevents spreading of bonnet end of body when screwing down the bonnet tight. It's SAFE, SURE and STRONG.

For your protection against substitutes always look for our name cast on the body of every genuine Penberthy Valve.



"OUTSIDE BONNET CONSTRUCTION"

Strong Where Others Are Weak

We Make:

The Compodisk Line (with the Renewable Disc)
Gov't approved for 175 lbs. steam pressure

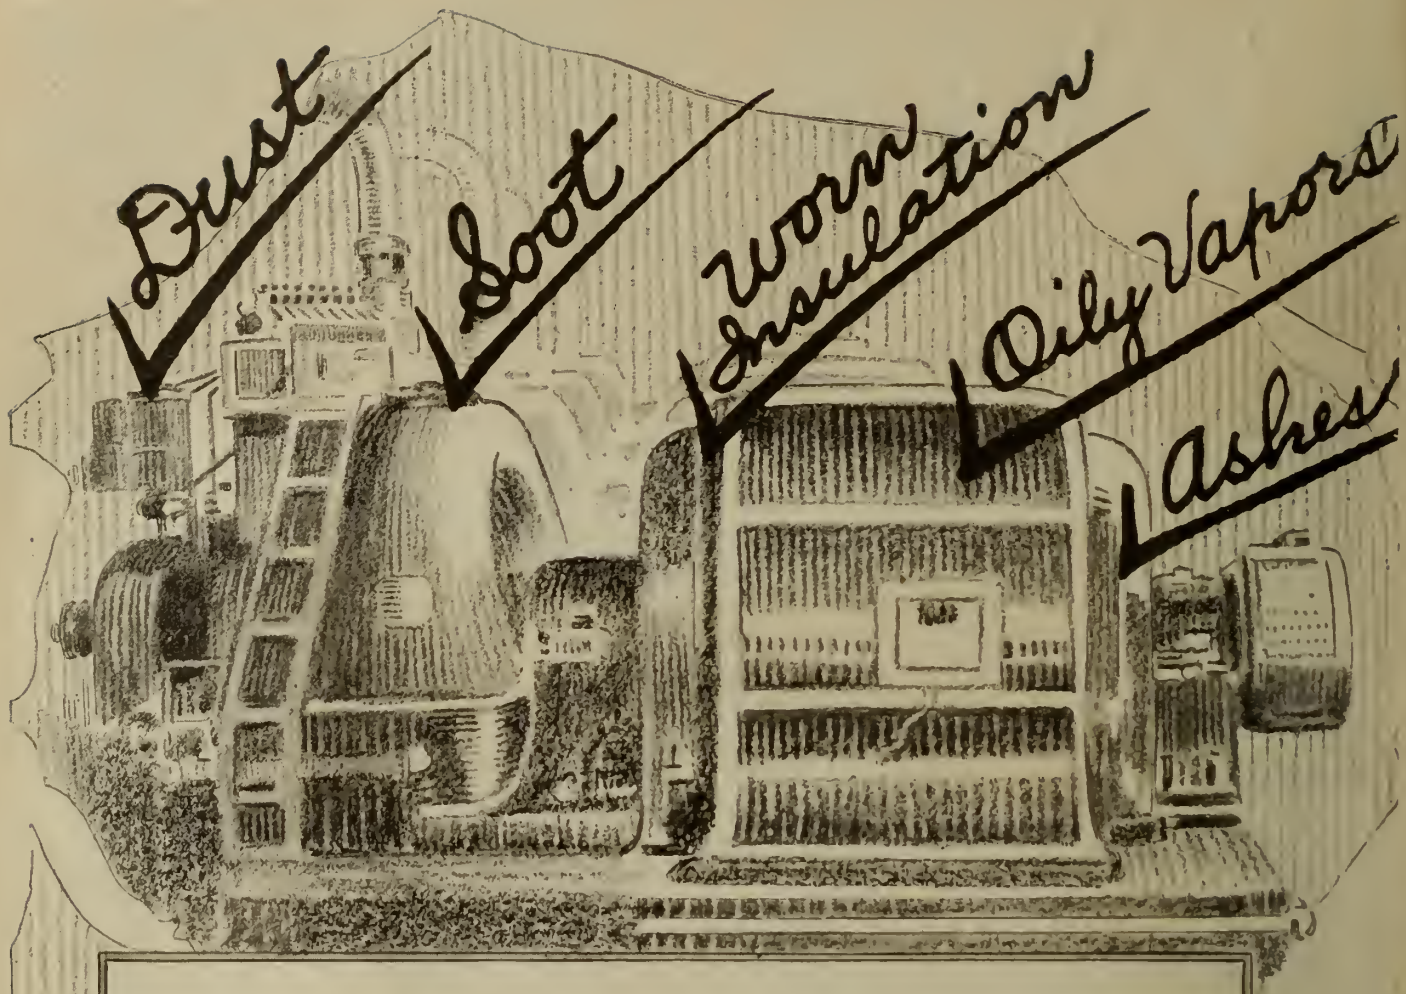
The Regrinding Line (with the Metal Disc)
Gov't approved for 200 lbs. steam pressure

Brass Gate Valves (with the solid Wedge Disc)
Gov't approved for 150 lbs. steam pressure

USED BY THE BEST ENGINEERS.

MANUFACTURED BY

Penberthy Injector Company, Limited - Windsor, Ont.



Banish Those Destroyers of Generator Efficiency

for they are the source of unlimited expense, trouble and losses. Lengthen the life of your generators and enable them to carry extra loads by installing

Sturtevant *Trade Mark* **AIR WASHERS AND COOLERS**

They allow no dust, oily vapors, soot, ashes, etc., to come in contact with the moving parts, and consequently eliminate the expense necessary without them for cleaning and repairs.

Sturtevant washers are solidly, simply and rigidly constructed. Nozzles easily and quickly cleaned. The large orifice on the nozzle prevents clogging.

A bronze fitted centrifugal pump is furnished with the washer for recirculating the water through the nozzles.

Send for our Catalog No 22620; in it you will find an explanation of why washers for 250,000 K. W. were sold in one month and why they are successful in so many hundreds of large plants today. It describes fully the various sizes and advantages. Write today.

Waterous

BRANTFORD, ONTARIO, CANADA

Power & Heating Boilers

Proper steam production is essential in any power mill.

Waterous Boilers enjoy an enviable reputation for easy steaming and for economy in fuel consumption. The correct design of boiler settings is mainly responsible for this.

Whether you are burning coal, screenings, refuse, wood sawdust, gas or oil, we supply settings that burn it with the least labor and with best economy.

We build Heating Boilers up to 72" x 16', Return Tubular Boilers for power use, up to 165 H.-P.; settings, single or battery, in brick or all-steel.

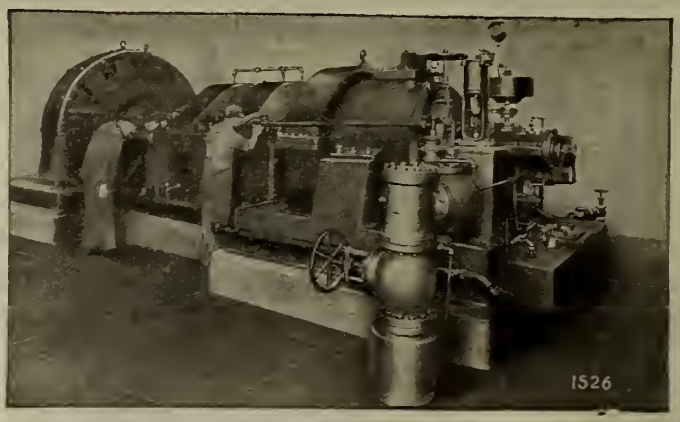
Power *For* Auxiliaries



THIS 1500-KW., De Laval geared turbo generator supplies direct current for the operation of auxiliaries in the Delray Plant of the Detroit Edison Company. The turbines operate on steam at 225 lbs. pressure and 210 deg. F. superheat. The steam is exhausted into a varying vacuum of from 24" to atmospheric exhaust. The condenser is a barometric condenser and the circulating water used is the condensate from the main generating units.

This arrangement gives high plant economy combined with the flexibility and easy control of electric driven auxiliaries.

In such service high efficiency and reliability are paramount. Every De Laval unit is guaranteed as to efficiency and is thoroughly tested at our works before shipment. Our engineers have had extensive experience in adapting the steam turbine to increase plant efficiency and would take pleasure in applying their information and skill to your conditions.

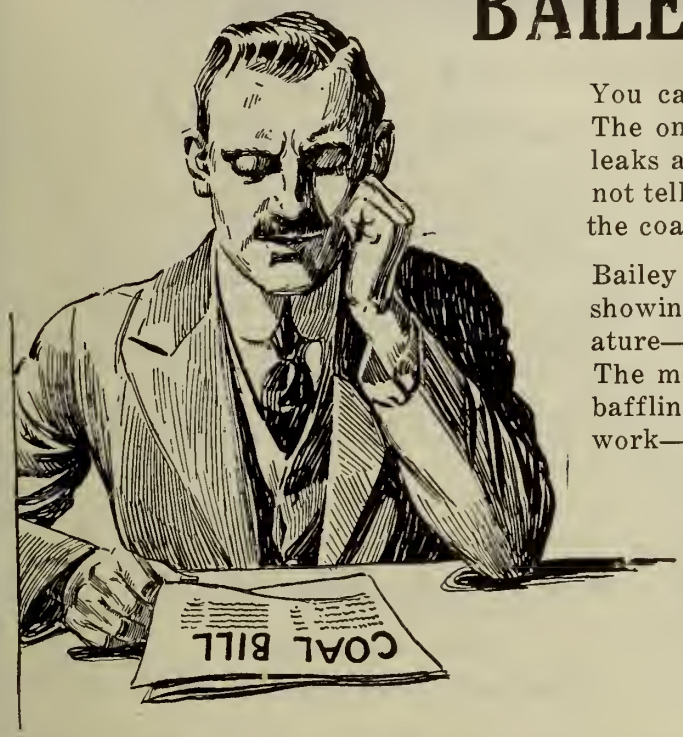
LEONARD

He Wouldn't Have This Worry if He Had BAILEY Boiler METERS



You can't eliminate coal leaks until you locate them. The only way to remove coal bill worries is to find the leaks and **then** go about eliminating them. Instinct will not tell your fireman just how well each boiler is burning the coal fed to it. The best he can do is **guess.**

Bailey Boiler Meters enable them to **know exactly** by showing the Steam Flow, Air Flow and Flue Gas Temperature—on the one chart. A lagging boiler is shown up. The meter tells whether excess air, fouled tubes, broken baffling or choked fires is the cause. There is no guesswork—the facts are right before them all the time.

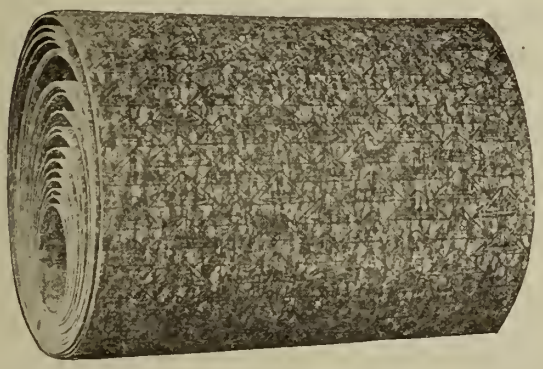
Write for bulletin.

Bailey Meter Company

2001 E. 46th St., Cleveland, Ohio, U.S.A.

Durabla Gaskets Make Tight Joints

Extreme tests prove that Durabla Gaskets can withstand all Temperatures and Pressures without showing signs of Distress.



Wherever a permanent Gasket is required use Durabla. Durabla Compressed Asbestos Fibre Gasket Material makes tight joints on Steam, Water, Air, Oil, Ammonia and Acids. It will not burn out, blow out or pulp at the joints. Durabla is made in convenient size sheets that can be rolled and unrolled. Stamped with the Durabla trade-mark which guarantees strength, goodness and quality.

New Truths and Old Fallacies

Lubricating Quality

As we have already tried to make clear, the self-lubricating quality of a babbitt is quite as important, if not more important, than the quality of mere hardness, as the lack of the former quality will nullify any advantage of the latter. It is only necessary to compare tin and lead by touch to note the dry, harsh feeling of tin and the natural lubricating quality of lead. The particles worn away by the shaft from the surface of a tin base metal do not act as those worn from the surface of Magnolia metal, as the latter are usefully expended in filling in the interstices of the shaft and imparting to both shaft and face of bearing a hard glassy surface, and after this conditioning the wear is so slow as hardly to be appreciable after years of service, and there is no seizing or scoring even though the shaft may be bedded down on a rough cast bearing or the lubrication deficient.

Thermal treatments play an important part in manufacturing babbits, in various ways, in relation to structural changes, and, if not understood, can change the crystalline formation from spherical fragments, which have a beneficial effect, to angular fragments, whose sharp cutting edges induce wear, heating and frictional resistance.

As no one can form an accurate judgment of a babbitt's value from its appearance, which does not disclose the knowledge and skill employed in its manufacture, such metals have to be bought on faith or reputation, or as is frequently the case, price is the deciding factor.

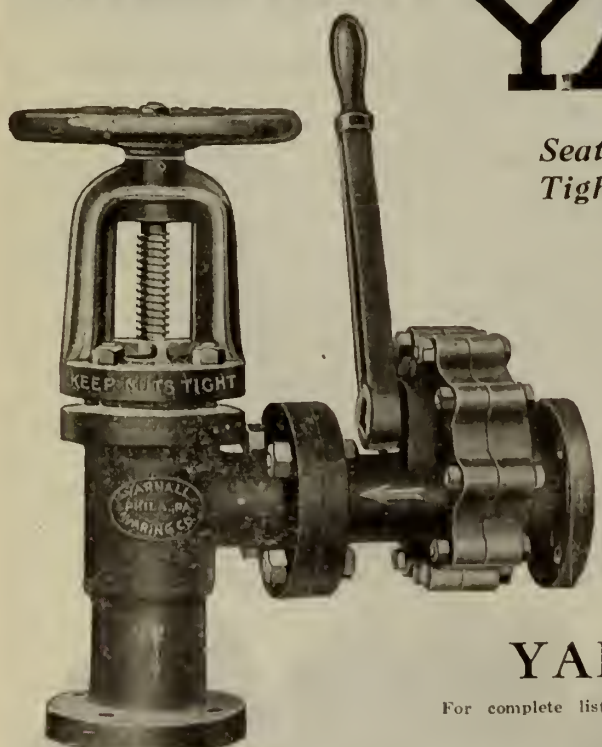
YARWAY



Seatless Blow-off Valve and Double Tightening Valve in Tandem Arrangement

A combination first developed to meet A. S. M. E. boiler code and boiler laws in certain states—that is ideal for blow-off service in any state.

The Yarway Blow-Off Valve is a slow opening, seatless valve that does away with the seat troubles of the old type valves and that automatically tightens the packing after the valve itself has closed, and releases the packing before valve starts to open.

The Yarway Double-Tightening Valve is a quick opening valve with the unique feature of a sealing bushing, (8, above sectional view) on the inlet side which makes the valve double tightening on both sides of the swing gate. With both valves in place the blow-off line is doubly guarded. Highly successful installations of this type are numerous. B-410 is a handy booklet that will show you the unusual features of the Yarway Valves in detail. To whom shall we mail it?

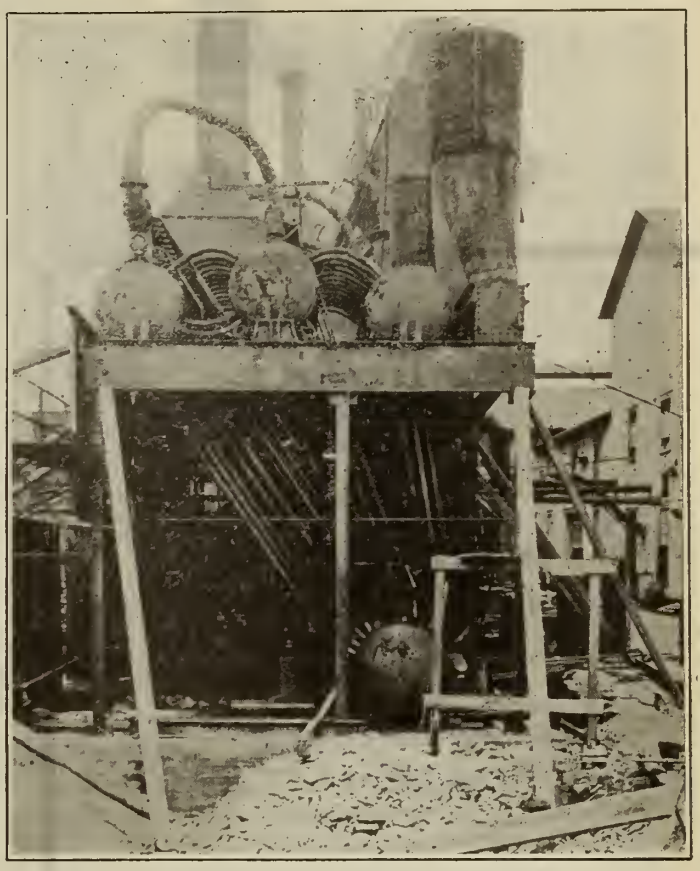
ELESCO

Advantages

The inlet of the saturated steam and the outlet of the superheated steam are located on opposite sides, to insure uniform steam distribution.



Typical installation of Superheater to Sterling type Boiler

THREE ECONOMIES OF SUPERHEAT

Economy is the demand of the hour.

Every expenditure must be a justifiable investment, one that will yield the fullest return.

Nothing you can add to your power plant for more effective power generation will yield a higher return per dollar invested than Elesco Superheaters.

The return from an **ELESCO** superheating investment is three-fold:

A saving of from 10 to 20 per cent. of the coal bill.

An increase in the boiler capacity.

A more efficient boiler which operates at a lower rate when the load is heavy.

You can measure the income on your ELESCO Superheater investment. It is tangible.

Bulletins explain why. Send for them.

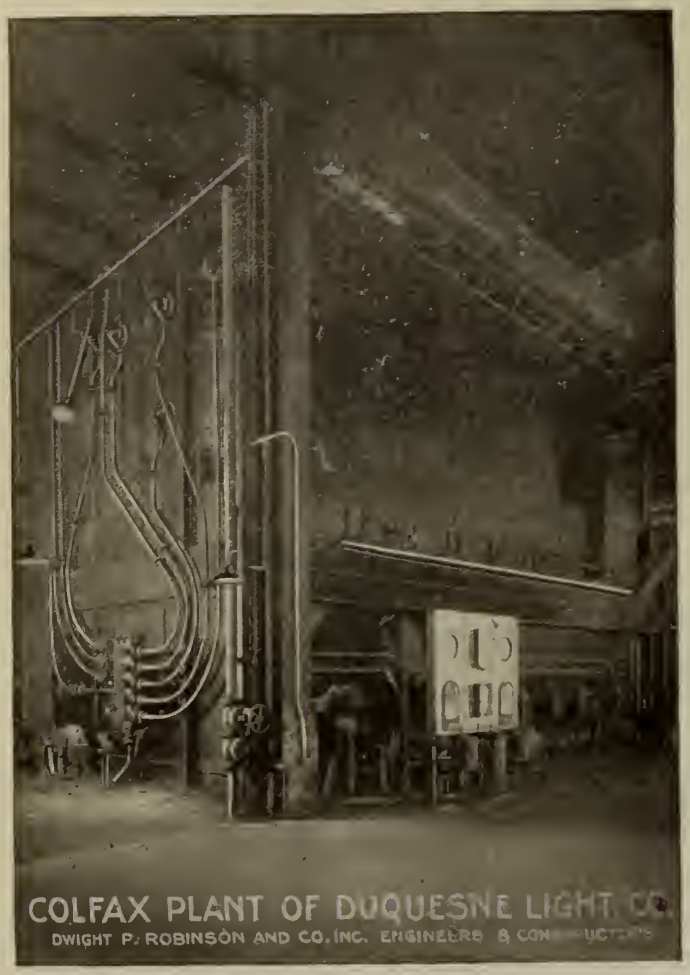
ANDERSON STEAM TRAPS

From the day you install an Anderson Steam Trap you will notice a difference. That difference lies in its absolutely tight action. Never will you find an Anderson that fails to deliver *dry steam* under every condition. It is positive proof against break-downs from accumulated moisture. Our catalog contains a full description of the Anderson—Write for it to-day.

The V. D. ANDERSON Company
1935 West 96th Street, Cleveland, Ohio



Blowing 20,876 sq. ft. of Heating Surface

It is just as easy and convenient to blow the soot and ashes from the immense heating surface of the Colfax boilers as it would be if your boilers were also equipped with Diamond Soot Blowers. Size of unit, extra width or type of boiler cannot affect the high efficiency and the thoroughness with which the soot is removed.

Clean heating surfaces save coal and increase boiler capacities. That is why the leading central stations and modern industrial plants have found it extremely economical to install Diamond Soot Blowers.

Let us tell you what they will do in your plant. Write for Bulletin 280.

Diamond Power Specialty Co.

Diamond

SOOT BLOWERS - SAVE 4 to 8% FUEL

A Time Clock *and* Recording Thermometer in ONE

The Columbia Recording Thermometer with the new TIME PUNCH does double duty—a two-in-one-instrument. In addition to furnishing an automatic day and night record of every variation of temperature in your heat-treat process, or the regulation of heat for any purpose—it also gives a constant check on the "human element"—shows whether the man responsible for temperature control has been watching the temperature record as he should—whether he has been on the job.

Every time the operator inspects the temperature record he presses the Time Punch—and the hour and minute of his inspection is instantly recorded on the record dial. If he neglects to make regular inspections, the dial shows his delinquency. While if he makes his inspections but neglects to correct any undue fluctuations in the temperature the testimony of the dial leaves him with no alibi or excuse.

Knowing that the dial will always tell the tale, both the conscientious and the careless operator are going to toe the mark, thus insuring a more uniform temperature—and avoiding the spoilage and damage which so often result from forgetfulness and neglect when you have no way of keeping tabs.

Columbia Recording Thermometers with Time Punch attachment cost no more than for an ordinary recorder alone.

Simple, direct and positive in their action.

Every instrument rigidly inspected and guaranteed. Any temperature up to 1000° F. can be recorded accurately.

This Time Punch is also furnished on Columbia Recording Gauges and Tachometers.

If you wish to eliminate spoilage, increase efficiency and cut manufacturing costs you should read Columbia Recording Thermometer Catalog H-33. *Write for it today.*

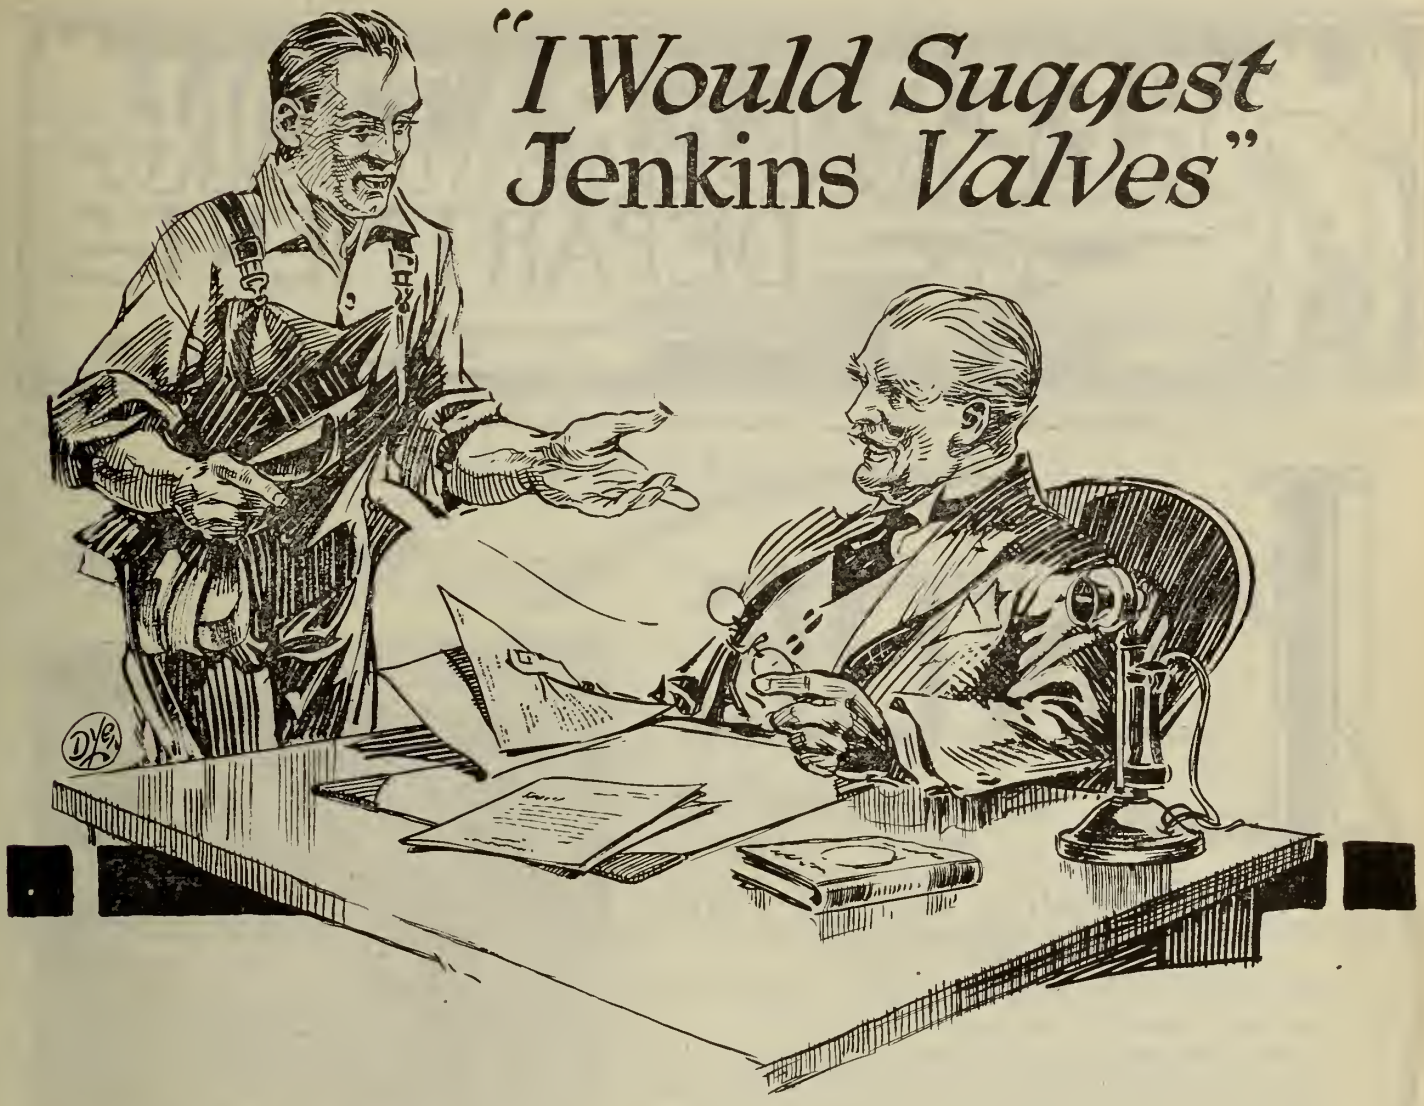
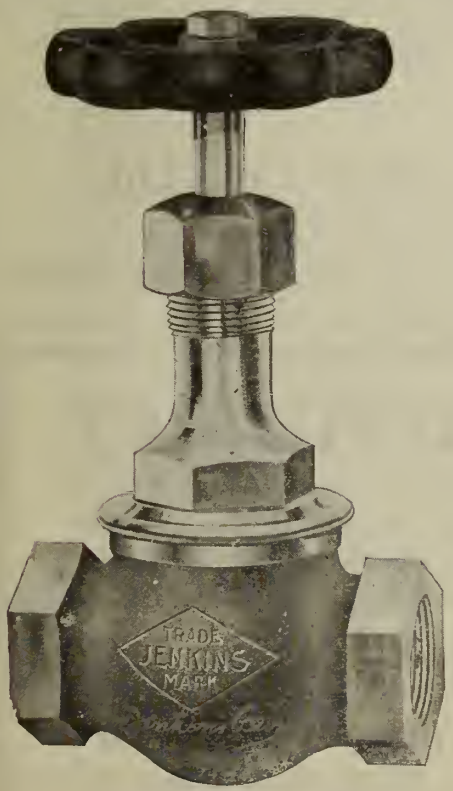
"I Would Suggest Jenkins Valves"





WHEN the inevitable breakdown—occasioned by inferior valve equipment—occurs, the Engineer who knows valves and valve requirements will invariably suggest Jenkins Diamond-Marked Valves.

Unpleasant reminders do not follow the installation of Jenkins Valves. Made strong and heavy and made of the best brass, iron or cast steel, they remain dependable and unaffected when subjected to the strain of hard usage and severe service.

Jenkins Diamond-Marked Valves are made in a size and a style to completely control the passage of steam, water, air, gas and other liquids or vapors.

Obtainable at supply houses everywhere.

LINDE

Made in Canada

REFRIGERATING AND
ICE MAKING MACHINERY

For Refrigerating and Ice Plants, Large and Small.

Mechanical refrigeration scientifically applied yields increased returns to the user.

Linde Refrigerating and Ice Making Machinery offer every improvement and convenience. Our new vertical enclosed type machines are designed for plants from 1 to 30 tons. Then for demands calling for loads up to 300 tons, our horizontal frame type is guaranteed to give better service than any other equipment on the market.

This 100-ton plant was designed by our engineers. These men are at your service. Designs, specifications and estimates upon request.

In the LARGEST and MOST MODERN PLANT in the WORLD, building Insulated DOORS and allied products exclusively, we are building what we KNOW to be THE BEST INVESTMENT FOR THE USER and the universally recognized WORLD'S STANDARD DOORS. In verification:—

THE HARRIS ABATTOIR CO., Ltd., Canada.

"Our Coolers and Freezers are mostly equipped with your doors. In fact we adopted it as Standard throughout our plant, as we find them substantially made and the insulation perfect. We also find the Hardware stands up better than on any other door we have seen or tried."

LOUISVILLE SOAP CO., Louisville, Ky.

"Coolers at one of our plants are equipped with your doors, which have given us such satisfaction we wish to improve the doors at our old plant. We would not be warranted in throwing out the doors but would like the type hardware you supply."

THE WASHINGTON MARKET, Washington, D.C.

"The doors supplied by you, in use at both plants, have been in every way satisfactory, and we think the Jamison door is the best on the market."

Read 'em again, men—analyze them! Acquaint yourself fully with our method of construction through latest catalog No. 10—just off the press.

Jamison Cold Storage Door Company

Formerly Jones Cold Store Door Co. **HAGERSTOWN, MD., U.S.A.**

In this hardening room of the Detroit Creamery Company, Detroit, Mich., the Nonpareil Corkboard Insulation of walls, floor and ceiling is 8 inches thick.

Insulation Saves Refrigeration

Except in very well insulated rooms, far more refrigeration is used to carry off the heat that leaks in through walls, floors and ceilings than to cool and keep the goods stored. The more this inflow of heat can be reduced by adequate insulation, the less refrigeration will be required.

The recognition of this fact is evidenced by the increasing tendency of refrigerating engineers and operators to use Nonpareil Corkboard Insulation in greater thickness than formerly. In many modern plants, operating economies have been found to justify fully the insulation of hardening rooms and sharp freezers with 7 inches or 8 inches of Nonpareil Corkboard. Increasing the thickness, and consequently the efficiency, of the insulation does not proportionately increase its cost. No more labor or materials, other than the corkboard are required to install 2 layers of 4-inch than for 2 layers of 3-inch. The remarkable ability of Nonpareil Corkboard to resist moisture and hence to retain indefinitely its initial heat retarding value spreads the investment over a very long period.

Its insulating efficiency, structural strength and durability have established Nonpareil Corkboard as the most economical insulation. To secure its maximum value, see that the thickness is adapted to your peculiar conditions of temperature, exposure and refrigeration cost.

The Company's engineers will gladly co-operate with you in working out the most economical thickness for your particular conditions. There is no charge for this service. Much valuable information on insulating cold storage rooms will be found in the 152-page book, "Nonpareil Corkboard Insulation," which will be sent free on request.

HOMESTEAD
Quarter-Turn Valves
Economy!

A valve to be economical must give dependable, lasting service.

Homesteads open and close easily. The patent balancing parts insure it against sticking. When the Homestead is fully opened, the two surfaces which are depended upon for tightness are in no way affected by the material passing through. The plug cock provides a straightway opening which is desirable in all sorts of work but particularly so in high pressure service—also in the handling of thick heavy liquids.

Elimination of waste time and leakages quickly pays for all Homestead valves. You would do well to adopt them without delay.

Homestead, Pa.

QUALITY YORK SERVICE

York Semi-Enclosed Refrigerating Machines

The Raw Water Ice Plant is rapidly taking the lead, and its development demands an Ammonia Compressor that is most economical in Power Consumption.

Where electric current is available at a reasonable cost, our Semi-Enclosed Machine, with direct motor mounting, makes a neat, clean and highly economical plant—no belts, no engine or steam lines.

The machine occupies a comparatively small floor space.

All the power developed by the motor is delivered to the crank-shaft of the machine.

These machines are built in sizes from 30 tons refrigerating capacity upwards.

WEIR AUXILIARIES

Every Part Built to Standard Means Uniform Service

There are three big reasons why a pump might fail to give satisfaction. Either it is not built right, it is the wrong type for the job or else the manufacturer fails to supply it with proper adjustments.

Weir Methods of manufacture eliminate all three of these possibilities. Weir pumps are built right; (65,000 users all over the world will tell you that). Weir Engineers analyse your requirements carefully and supply the pumps that fit. Weir method of standardizing all parts is the customer's guarantee that any new part will fit as perfectly as the old one.

In addition to a complete line of Pumps Weir products include Multiflow Heaters, Direct Contact Heaters, Evaporators and Distillers. Write for literature.

A Great C. A. S. E. Convention in Ottawa

The Convention from Every Point of View Was a Great Success —A Large Number of Exhibitors Were on Hand, and the Entertaining Was Well Taken Care Of

THE MONTH of June is noted for leafy trees, June brides, and the C. A. S. E. Convention, and the month just passed was no exception in any of these features, We don't know if there were any more leaves than usual, or any more brides, but we do know that the Convention was one that has to be described in superlatives. In spite of the weather man, who did his best to sap the energy of all those in attendance by turning on an extra dose of heat and humidity, interest never laxed from the time the convention was declared open till the last function took place on Thursday, and every event on the programme was carried off in great style, with lots of enthusiasm.

The convention headquarters were at St. Patrick's Hall, Laurier Avenue, right opposite the recreation grounds, and close to the Armory. The hall is situated only about five minutes walk from the station and the principal hotels, and was very well chosen for the purpose. The exhibition of power plant supplies was placed in the main hall, while the delegates to the Grand Lodge C. A. S. E. held their deliberations in a suitable room upstairs.

The Opening Day

The opening day, Tuesday, June 28th showed a scene of great activity in the Hall, where the finishing touches were being put to the exhibition by the various representatives of the firms occupying space. The booths were much further ahead than is usual at this stage of the proceedings, and there is no doubt that a great deal of work had been put in on the previous day to have everything ready for the opening.

The Grand Lodge went into session at 10 A. M. prompt, and remained in the meeting until 11 A. M. when they came down to meet the exhibitors and to perform the opening ceremonies. The chair was taken promtly at 11 A. M. by Mr. Leach, President of the Grand Lodge, and on the platform with him were Mr. Earl Hethrington, of Goldie McCulloch & Co, chairman of the Exhibitors Association Entertainment Committee, Mr. C. B. Turner, Chairman of the Exhibitors Association, Mayor Plant of Ottawa, and the secretary of the Ottawa Lodge. This gentleman introduced Mayor Plant to the delegates, visitors and exhibitors in a few words, which were however fully appreciative of his worship. Mayor Plant then formally welcomed the convention to Ottawa, and gave them to understand that the city was theirs. He dwelt with pardonable civic pride on the many attractions which the capital boasts, and then went on to mention those of the little industrial city across the way, which as is well known, has some special features of its own. The worthy Mayor, who is evidently not one of those who voted dry, spoke with appreciation of the comfort to be extracted from a visit to Hull, and then with great thoughtfulness, told the gathering that he had given the police instructions to the effect that anyone wearing the badge of a visitor, delegate, or exhibitor, at the convention, was to be immune from any interference, even if their behavior should be strange. We are glad to say that the safe conduct thus kindly furnished by the Mayor did not have to be used, those who patronised the trip to Hull being evidently well fortified and able to stand it without any signs of wear. This of course was to be expected of the delegates from Montreal, but it was a very creditable showing for those who came from regions that have been more or less dry for some considerable time, and thus without the opportunity for steady training.

The Mayor was loudly cheered at the conclusion of his speech of welcome, the audience rising en masse and singing "He's a Jolly Good Fellow" and singing it with real heartiness. Short speeches followed from Mr. Leach and Mr. C. B. Turner, the latter calling attention to the excellence of the exhibition which he said considered as a purely power plant proposition, was the biggest thing in Canada. A few words from Mr. Hethrington concluded the opening ceremonies, and the convention was away to a good start.

iness session of the engineers, and at 4

The afternoon was devoted to a business session of the engineers, and at 4-P. M. a visit was paid to the exhibitions. During the afternoon the Deputy Minister of Public Works in the Federal Government together with some of his staff paid a visit to the Hall, and was much interested in the various appliances and apparatus that were on view. There was much to interest any one who came, and it is pleasing to note that quite a few outsiders availed themselves of the opportunity as well as the engineers and their friends.

The evening was given up to a trip out to Aylmer, the drive being very welcome after the torrid heat of the day. There is no doubt that Ottawa deserves its reputation of being the hottest in summer and the coldest in winter of all Ontario's cities, and the long run out in the beautiful country surrounding the city was much appreciated. Some of the more energetic staged a little dance when they arrived at the Park, but for the most part the visitors were glad to stroll around and enjoy the cooling breezes, and gain strength for the coming day.

TheExhibition

Before going any further it would be well to pause and give some time to the exhibit, which was pretty unanimously termed the best ever. That verdict was well deserved, and the trouble gone too by some of the exhibitors to make a good showing deserves a great deal of credit. There is no person outside of those actually engaged in the work, quite realises how much trouble and expense are incurred in these exhibitions, or how many months of preparation are needed to make them a success. However we think that on this occasion the efforts of the exhibitors were well appreciated, and more attention given to the booths and their contents than on some other occasions. It was a liberal education for any engineer to stroll around that Hall, and see the number of things that have been developed and perfected for the better operation of the plant that he has charge of.

The following firms were represented by exhibits in the Hall:—

..Crane Ltd. Montreal, showing a full line of valves, fittings, and steam traps. A large pipe bend was a feature of this exhibit.

The Underfeed Stoker Co.. Toronto, showing a model of their underfeed stoker and a working model of the cole stoker regulator.

Darling Bros., Montreal, showing a full line of heating specialties.

The Garlock Packing Co., Palmyra, N. Y. with a full line of high and low pressure, steam and hydraulic packings.

Beveridge Supply Co., Montreal, special refractory cements.

Ogilvie Bros., Montreal, Patent high andlow water alarm, aperated on an electrical system without the use of any floats or wdrking parts.

W. R. Secton Boiler Setting Co., Toronto, showing Nonpareil fire grates etc.

The V. D. Anderson Co., Cleveland, showing steam trap.

The Dunlop Tire and Rubber Co., rubber goods.

The Imperial Oil Co., Toronto.

Babcock and Wilcox. Watertube Boilers, mountings etc.

Canadian Allis Chalmers, Toronto.

Instruments Ltd., Ottawa, showing a very complete line of heat measuring instruments, electrical CO2 recorder, pyrometers,etc.

Power House, Toronto.

Canadian Manufacture, Toronto.

Power, New York.

C. B. Turner & Co., Toronto, showing a number of samples of scale etc, taken from boilers by his process.

Dominion Flow Meter Co., Toronto, showing steam flow meters, etc.

France Packing Co., Philadelphia. Patent metallic packing.

Dearborn Chemical Co., Toronto.

George W. Cole Ltd., Toronto, showing Cole traps and Monash valves.

J. A. Langelier, Ottawa, showing Lunkenheimer valves.

Dart Unions Ltd., showing union joints.

Westco Pump, Toronto, showing motor driven centrifugal pump.

Quaker City Rubber Co., Philadelphia, showing P. P. P. packing.

Jenkins Bros. Ltd , Montreal, showing a full line of valves.

James Morrison Brass Mfg. Co., Toronto. Steam Gauges, reducing valves, injectors and valves of all kinds in brass.

The Second Day

The morning of Wednesday opened with ominous clouds, but just as much heat. The forenoon was devoted to a business session of the Grand Lodge, and a further visit to the exhibits. The afternoon had been set apart for a motor drive around the cty, followed by the annual sports at Lansdowne Park. However, this programme did not seem to suit the weather man, who sent along a severe thunder and rain storm, and effectually cancelled the proposed drive. Not to be daunted however, the entertainment committee of the Exhibitors Association arranged for the use of Howick Hall for the sports, and they were held accordingly. In spite of the heat, which was no less following the rain storm, all the events were run off, and a very meritorious performance put up by the various contestants.

The following events were run off:—

100 yards dash:—Won by J. Thompson, Toronto.

Thread and Needle Race:— Won by Mrs R. C. Leach, Toronto.

Donkey Race:— Won by Grant. E. Cole, Toronto and W. E. Fyfe, Montreal.

Married Ladies, Race:— Mrs Edge.

Backward Running Race:— George F. Galloway.

Ladies' Clothes Pin Race:— Muriel Berry.

Men's Smoking Race:— G. F. Holloway.

Charm Race:— Mrs Edge.

Wheel Barrow Race:— Grant E. Cole and W. E. Fyfe.

Little Boys' Race:—Charlie Clark.

Little Girls' Race—Olive Berry.

The ball game was won by the Exhibitors by one run.

The starter was of course George Moll of London without whom we doubt if the sports could go on. Messrs Lyon and Keith acted as judges and Mr. Hethrington as Director.

The Evening Concert

The evening concert which followed the afternoon's strenuous excitement, was a real delight to all those who braved the heat of the Hall to hear it. Expressions of surprise were heard from several who have not had the opportunity of being present at one of these entertainments, at the excellence of the talent which was revealed. Most of the old favorities were present, including Mr. Curzon of Montreal, Bob Jones, of Philadelphia, Mr. Jack Armour, the ever popular Jack, whose public entertainments are only surpassed by those he gives to the privileged few, and Earl Hethrington, whose tenor is as pleasing as ever. Besides these, four little pupils of Miss Dunlop of Ottawa, put on a Scottish dancing turn which brought down the house. There were two little boys and two little girls, and to the skirl of the pipes, they went through a long dance and encore in all their heavy Highland accoutrements, with vim and dash, when most of the audience were hot just looking at them. They received a great hand when they finished, and repeated their performance in the second half of the programme.

After the concert was over, the prize drawing was held, and this furnished as much amusement and pleasure as it always does. The lucky man to receive the handsome meerschaum pipe donated by Mr. C. B. Turner was George Nicholson. Ottawa.

After everything else was done, some of the more intrepid spirits started a little dance, and kept it up for an hour or so, not being willing to leave anything undone that could possibly be done. We understand some of the boys didn't even conclude with the dance, but this being only hearsay, we will not dwell on it. Knowing some of them as we do, we are inclined to think that there may have been something in it at that.

Get Away Day

All good things have an end, so with the coming of Thursday morning preparations for departure were very much in evidence. The engineers ascended to their upper chamber to carry on the election of Grand Lodge officers for the ensuing year, and to decide on a place for next years Convention. While the engineers were thus busy, the Exhibitor's Committee held a meeting to elect their officers for the coming year also.

The following gentlemen were elected to office in the Exhibitor's Association:—

Past President:— C. B. Turner, Toronto.

President:— Grant Cole, Toronto.

1st Vice President:— E. B. Curzon, Montreal.

2nd Vice President:— J. Thompson, Toronto.

Treasurer:— Lloyd E. Archibald, Toronto.

Ass. Sec. :— Bob Jones, Philadelphia.

Chairman Entertainment Committee:— Earl Hethrington.

Chairman Exhibitor's Committee:— R. A. Lyons, Toronto.

It was voted that a letter of thanks be forwarded to Bob Jones, E. B. Curzon. Jack Armour. Mr.Marchand. Mr. Dickson for their services to the entertainment. A standing vote of thanks was also given to Mr. C. B. Turner the retiring president for the efforts he had put forth to make a success of the exhibition. Mr. Lyons made some suggestions along the line of getting a still bigger exhibition for next year. The meeting concluded with a song from Bob Jones, and expressions of satisfaction over the success of the convention.

The Grand Lodge officers of the C. A. S. E. for the coming year are as follows:—

President Bro F. Harper. Kingston
Vice President H. Wright, Montreal.
Sec. Treas. L. J. Ellis, Hamilton.
Cond. G. W. Galloway, London.
Doorkeeper R. Rodney, Ottawa.

It was decided that Kitchener should be the convention town next year, that go ahead community having extended a very hearty invitation to the Grand Lodge to come there.

So ended a convention that looked at from any angle was a source of satisfaction to those participating. The delegates and visitors had the opportunity of seeing a first class exhibition of power plant appliances, and the exhibitors had the satisfaction of knowing that their exhibits were viewed with interest, and though direct results are not looked for, some of them received even this. Next year's convention at Kitchener will be, if the efforts of those concerned can so make it, even better than this one, and we hope it will see a bigger, stronger and ever growing C. A. S. E.

A Description of the Bettington Boiler

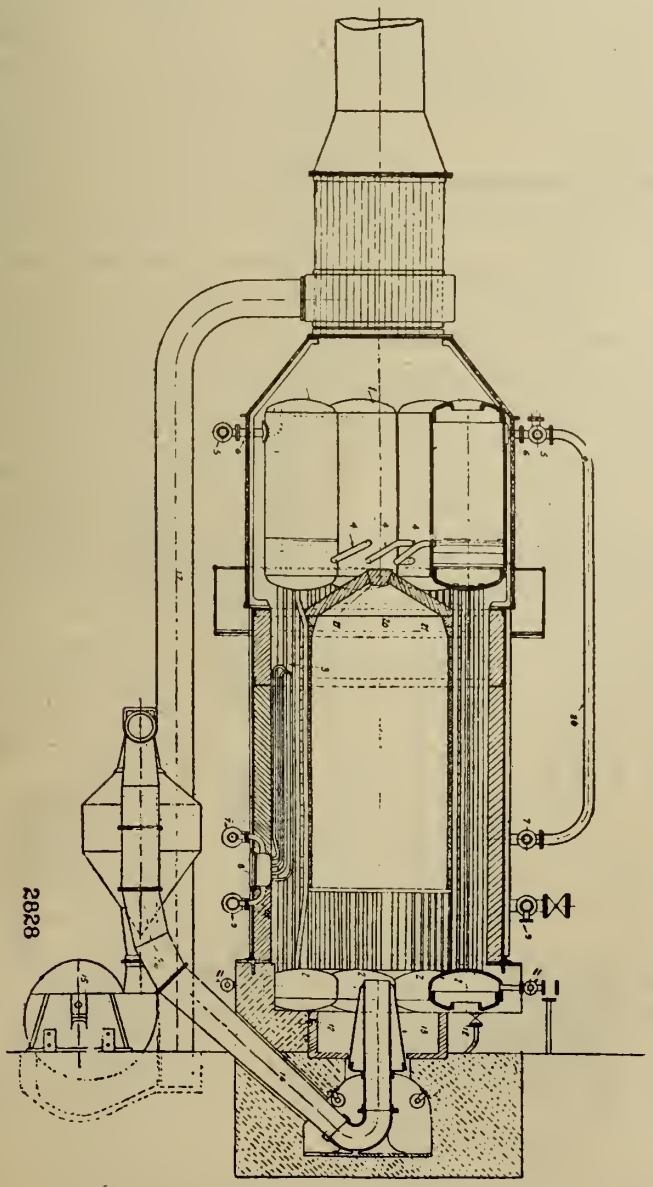
This boiler has been designed to burn pulverized coal, oil, or gas, and other atomized combustibles. For this description we are Indebted to "The Engineer," London.

THE Bettington water-tube boiler is designed to use pulverised coal, oil, gas and other atomised combustible substances. Introduced originally before the war, the boiler, though it had passed the experimental stage and was giving satisfactory results on a commercial scale, did not satisfy the makers on all points, and investigations were in hand to improve the design when war broke out and put an end to further research on the subject.

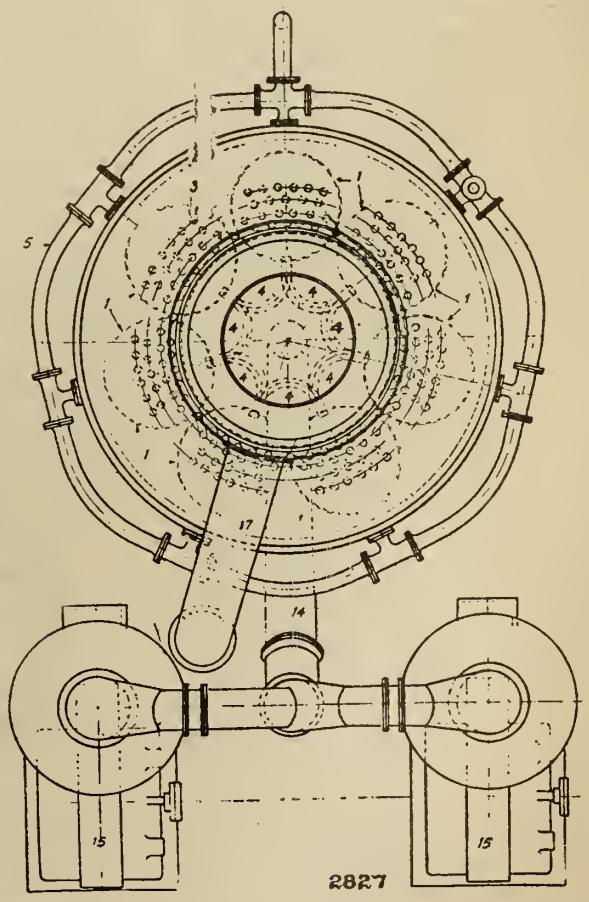
Opportunity has since been given to continue the investigation, and the makers (Fraser and Chalmers Engineering Works of the General Electric Company) have now brought out a new design, embodying the same principles, but altered in certain points to give greater strength and reliability.

A section of the boiler is shown in Fig. 1. The cycle of operations is as follows: Coal is fed from a hopper into the pulveriser, which consists of a rotor, fitted with manganese, steel beaters on the periphery. The pulveriser also acts as a blower, and, after the coal has been disintegrated, it is delivered into the dust separating chamber, the fines passing direct to the fuel nozzle, the coarse particles returning by gravity to the pulveriser for further reduction. The air with which the pulverised fuel is mixed is pre-heated from the exhaust gases. The combustible mixture enters the furnace vertically along its central axis, and immediately passes into a high temperature zone. The momentum of the coal particles carries them upward in company with the central current of the hotter gases, when the most intense reaction occurs. The action of gravity ultimately overcomes the upward momentum of the coal particles and such of them as are not already completely consumed "mushroom" over, coming in contact with the relatively cooler brickwork and tubes forming the retaining walls of the furnace. By this time combustion is virtually complete, and the burnt out gases provide an enveloping sheath to the zone of most intense reaction, thus actually forming an indestructible lining of gas between the intense zones and the furnace wall.

The course of the burning particles of coal is such that they are constantly changing to a fresh supply of oxygen without any tendency to concentrate in more or less horizontal stream lines, as is the case when the momentum and gravity act at right angles to one another. The ash of the fuel in its passage through the zone of highest temperature is converted into a liquid spray. A portion of this liquid ash strikes the brick lining of the furnace, and, in time, trickles down to the bottom edge, being



SECTION ELEVATION



PLAN OF BOILER

kept in a molten state by the descending hot gases, till it finally reaches the lower or "dripping" edge of the furnace proper. Being unable to adhere to the water-cooled surfaces, it drips and falls clear to the ashpit, which, being relatively cool chills it sufficiently to prevent the succeeding drop from adhering to it.

The boiler itself consists of mild steel top and bottom headers, with solid-drawn steel tubes connecting them. A top and a bottom header with their connecting tubes form a distinct unit which can be removed and replaced without disturbing the other tubes and headers. Special bricks in combination with the innermost circle of tubes, form the wall of the combustion chamber, the water tubes preserving the bricks from melting by conduction and evaporation. A feature of the design is that it is possible to dispense with fireclay in the building of this brickwork, for the liquid spray formed by the ash of the burning coal forms, when it comes in contact with the furnace walls, a slag which hermetically seals all crevices and cements the lining into one solid piece, as well as glazing the inner surface as though with a smooth enamel.

The super-heater consists of vertical tubes running parallel to the main boiler tubes. As will be seen from the drawings, a sectional design has been adopted for the super-heater to allow of the speedy withdrawal and replacement of any damaged section. Owing to the complete combustion and the forced draught, only a small smokestack is required. The gases before entering the stack pass through an air-heater, and thereby give up some of their heat to the air, which is drawn through the pulverising fan and forced into the boiler with the fuel. This pre-heating of the air allows of the use of coals containing up to 15 per cent. of moisture. Slides are provided in the pulverising fan for regulating the amount of air, and the coal feed is operated by means of a variable speed friction wheel driven from the shaft and controlled by an adjustable slide in the hopper.

The method usually employed for driving the pulverising fan is by direct connection through a flexible coupling and motor, although steam engines and small turbines have been substituted in some cases with satisfactory results. To fire up the boiler when cold a lighted torch is placed above the fuel nozzle, the pulveriser started and the fuel feed turned on. After the fuel mixture has ignited, the torch is extinguished and the fuel feed set to the desired rate. After temporary stoppages it is sufficient to start the pulveriser and turn on the fuel feed when ignition takes place from the hot brickwork.

Among the advantages of the boiler, it is claimed that the amount of scale deposit is very much less than occurs in other types of boilers with more sluggish circulation and with horizontal water tubes in which the scale tends to settle on the lower side and form patches. The rapid circulation in the Bettington boiler ejects loose scale to the bottom headers, where it can do no harm, and is in due course blown out. Another advantage of the vertical tubes is that soot and dust do not accumulate on them and so cause a loss in heating efficiency. It is further claimed that, owing to the symmetrical construction and concentric method of fixing these boilers, all differential expansion strains are eliminated and no abnormal stresses set up when firing a cold boiler at maximum rate.

Two of these boilers are now being installed in the Fraser and Chalmers Engineering Works at Erith for electric power supply, and arrangements have been made in the shops to meet outside orders.

No figures are at present available of the performance on a full scale of the improved Bettington boiler, but it is hoped to have these figures as soon as the installation at Erith is completed. As allowance has been made in the new design for higher working steam pressures and greater efficiency in the superheater, combined with a higher reliability and safety factor than existed in the pre-war model, it is expected that a substantial increase in thermal efficiency will be shown.

PROPER CONNECTIONS FOR SHUNT-FIELD RHEOSTAT.

M. M. Beach.

(Copyright. All rights reserved.)

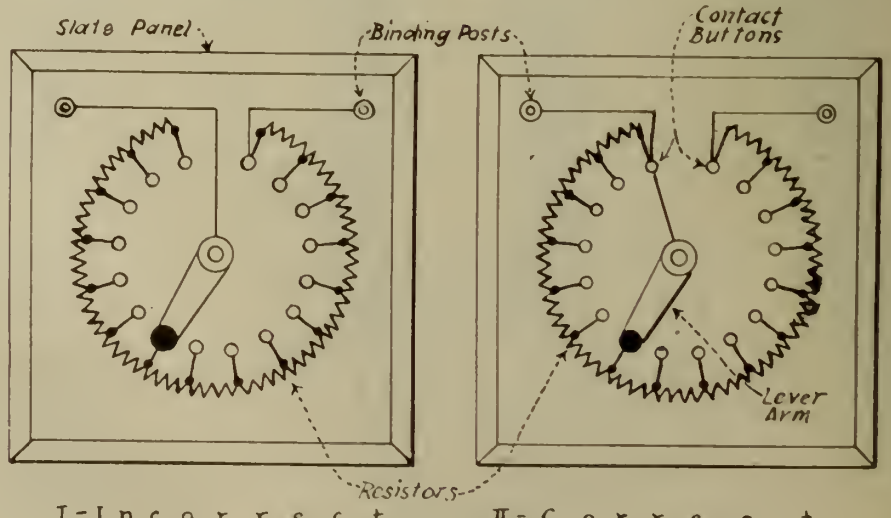
Difficulty may be experienced due to the fact that the lever arm on a shunt-field motor rheostat does not always effect good connection with the contact buttons. This may result in the opening of the shunt field circuit. Then, the motor will operate at abnormally high speed. In some instances such a trouble can be corrected by making a change in the connections. The general principle involved is illustrated in Fig. 1. If the connections are made as shown at II, the field circuit can never be open in the rheostat—even if the lever arm makes poor contact with one of the buttons. At 1, the incorrect method of connection, whereby the field circuit is open if the button contact is poor, is diagrammatically indicated.

A PORTABLE PETROL DRIVEN CRANE

Steam and electricity have hitherto been the chief means of driving cranes of a size larger than could be operated by hand, but the compactness and the convenience of the petrol engine have led recently to its application to cranes of the lighter grades. A good example of this new type is a portable crane developed by a British firm mainly for use in building operations. It is driven by a two-cylinder petrol engine and is made in two sizes, one capable of lifting half a ton and the other with a capacity of one ton. An important feature of this crane is the special gear which enables the driver, simply by moving a control handle, to lift a load at any speed from a crawl to the maximum, while the engine runs continuously at its most efficient speed. If for any reason the handle is released the brake is automatically applied on the instant and the crane comes to rest with the load suspended. The engine acts as a counterweight and the whole equipment is so light and well-balanced that it can be easily moved about on its four wheels or slewed as desired.

SUCCESSFUL BRITISH TRACTORS

The merits of the British-made tractor for agricultural purposes were conclusively demonstrated during a trial on a rubber estate in the Far East. All conditions were against success. The soil consisted of heavy sand or of sand mixed with clay, and rain had fallen heavily prior to the trial. Nevertheless the driver was able to turn and manoeuvre with the greatest ease. Further, the tractor showed its hauling powers by pulling two large trucks, weighing about 11 tons up the hill.



CORRECT AND INCORRECT METHOD OF CONNECTING RHEOSTAT

Recording Ash Pit Loss from Chain Grates

A description of a new device which enables the loss of combustible in the ashpit of a chain grate stoker to be noted and controlled by the fireman.

By E. G. BAILEY.

THERE has been more guesswork and less knowledge regarding ash-pit loss than any other thing of equal importance in the boiler plant. It pays to watch the ash pile from every kind of stoker or even hand-fired furnaces, though it be only visual inspection to note whether it is well burned out or full of combustible. To sample and analyze the ashes regularly and calculate the heat lost in that manner is better still, yet it is done in comparatively few plants and falls far short of accomplishing the desired result. A sample taken from the entire plant each day leaves the responsibility divided between the different firemen and different types of stokers. To take a sample from each boiler for each shift would still not accomplish as good results as if the ash-pit loss were continuously recorded for each boiler.

Instantaneous readings of any kind are most valuable in aiding the fireman to obtain results. He can then see a faulty condition as soon as it takes place or even starts to take place, and remedy it promptly. If such readings are recorded continuously the fireman can see how quickly the remedy is effective. Such records also show the executive in charge of the plant just what took place at all times.

It is the purpose of this paper to present some preliminary data obtained from a device recently developed to record the ash-pit loss from chain-grate stokers. It may later be extended to some other types of stokers of either the present or modified design, but the great need for it on chain grates led to its being applied to these first.

Method of Recording Ash-Pit Loss.

The fundamental principle used in recording the ash-pit loss by this method is to place a temperature-recorder bulb at a point near where the ashes are discharged from the active section of the grate or furnace. The bulb is not in contact with the ashes but receives only the radiant heat from the coke being discharged. The relation between this temperature and the amount of combustible in the refuse, and the heat loss due to it, is established by taking a series of samples corresponding to different temperature readings.

If the ashes are well burned out, so that there are no live coals, the temperature is comparatively low. Even though the ash has clinkered rather badly and retained a certain amount of temperature, it has usually lost its glow and is comparatively cold from a radiation standpoint. The coke coming over is still ignited and at a temperature of about 1800 to 2000 deg. Fahr., so that its radiant heat to the bulb is sufficient to cause very decided changes in the temperature readings.

In selecting a location for the temperature recorder bulb, it is necessary to have it shielded from any radiant heat of the furnace itself, and also as free as possible from changes in temperature due to the surrounding brickwork, circulation of air, etc. It is further necessary that the bulb extend across the entire width of the grate and be so constructed as to obtain an accurate average in case the amount of coke coming over is greater on one portion of the grate than another.

Fig 1 shows an installation on a natural-draft chain-grate stoker with a 9 ft. bulb located just beyond the water back, which shields it from the heat of the furnace. It is located about seven inches above the rear end of the grate so that the radiant heat from any coke passing under it will increase its temperature.

The Temperature Recorder.

The temperature-recorder bulb itself is made very rugged to withstand this service. It is constructed of 1½-in. steel tubing with ⅛-in. wall and all joints welded. The bulb is charged with nitrogen and the gas pressure that is exerted by an increase in temperature is conducted through a 3/16-in. copper capillary tube to the recorder. The recorder consists of a simple mercury U-tube, one leg of which is open to the atmos- recorder is attached.

The other leg of the U-tube is made up of sections having different cross-sectional areas so that the pen movement is suppressed below and above the range to be recorded on the chart. It is also possible, if necessary, to have the area of one leg of the U-tube variable so that the percentage of heat loss will be recorded directly with uniform gradations on the chart in case the relationship between the ash-pit loss and temperature should not be a straight line.

The bulb can be made in sections short enough to be installed where the alley between two boilers is narrower than the width of the boiler itself. Each section, however, is welded permanently with ¼-in. No. 13 gauge steel tube, making a flexible connection so that it can be folded up and then straightened out as it is installed in the furnace.

Up to the present time the experiments have been largely confined to the selection of the best locations for the bulb with respect to the grade and also to determine the relative advantage of bare bulbs and those having lagging around a portion of their circumference so as to minimize the heat received from or given off to the surrounding walls, air, etc.

Fig. 2 shows the location of a bulb at the end of a forced-draft chain-grate stoker. A bare bulb was first located at position No. 1 with cast-iron supports. It was found that when the fuel was up to the bottom of the water back and there was a slight positive pressure in the furnace, a flame would envelop the bulb, sending the temperature up to more than 1500 deg. No data were obtained from this recorder in the No. 1 position.

The bare bulb was next placed on the cast-iron bracket in position No. 2, and after operating several days it was found to be satisfactory as to temperature range and continuous operation. A series of calibration tests was then started to learn what combustible losses corresponded to the different temperature readings.

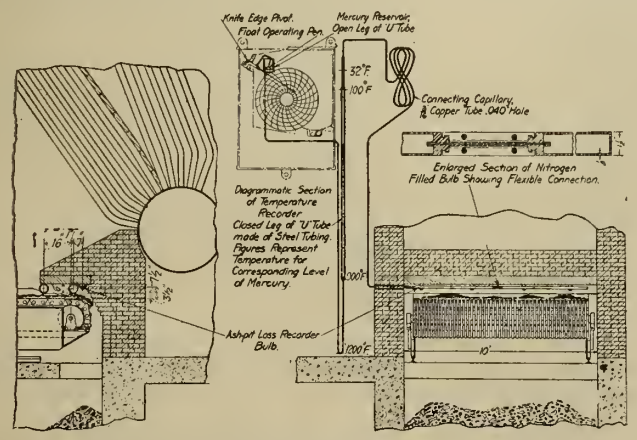


FIG. 1.—ASH PIT LOSS RECORDER INSTALLATION ON NATURAL DRAFT CHAIN GRATE STOKER.

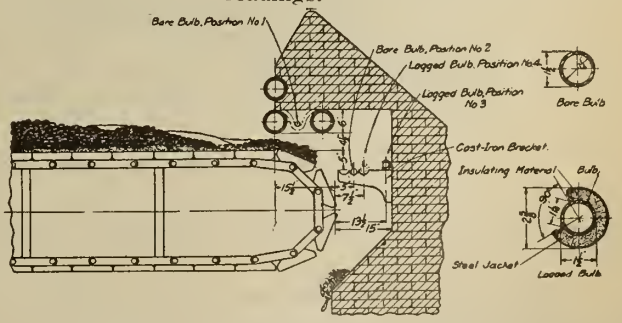

FIG. 2.—ASH PIT LOSS RECORDER ON FORCED DRAFT CHAIN GRATE STOKER.

Relation Between Temperature and Combustible Loss.

Samples consisting of all the ash discharged from the stoker were taken hourly. The ash as it accumulated in the hopper was quenched immediately by means of a water spray. At the end of the hour the ash was dumped from the hopper, crushed, mixed and quartered by hand until it was reduced to about 20 lb. of 4-mesh size, and sent to the laboratory. The analyses show combustible on the dry basis.

The samples from Station A were collected from time to time between January 20 and March 2, 1921, at times when it was convenient to do the work. Usually five to eight samples were taken each day. In all, 107 samples were taken during 15 different days. About half of them were taken during certain stoker tests that were being made on this boiler

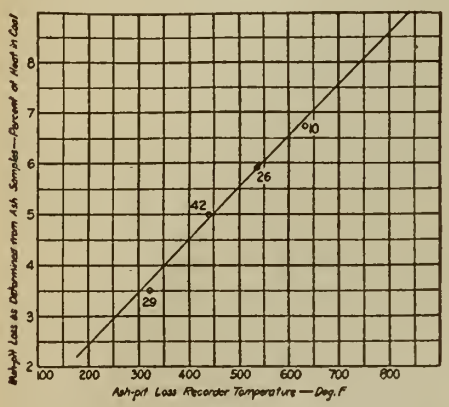

FIG. 3.—ASH PIT LOSS AND TEMPERATURE RELATION FOR BARE BULB IN POSITION NO 2. (FIG. 2) ON FORCED DRAFT CHAIN GRATE STOKER.

and the remainder under everyday operating conditions.

No special effort was made to change operating conditions from normal except in the case of a few samples, when more combustible was run over than usual in order to get some high points to establish the upper part of the curve.

The essential results for the 107 samples taken are plotted in Fig. 3, where each small circle represents the average of all temperature readings grouped between 300 and 400, 400 and 500 deg. Fahr., etc. It is noted that the ash-pit loss is about 3.5 per cent. at 300 deg. and increases 1 per cent for each 100 deg. temperature rise.

It was first thought best to plot the results between temperature and percentage of combustible in the ashes, but it was found that the ash in the coal varied between 8.5 and 14 per cent. From the curves of Fig. 4 it is noted that with samples having 30 per cent. combustible the heat loss is 3.9 per cent. from the 8.5 per cent. ash coal and 7 per cent. from coal with 14 per cent. ash, hence each test was figured on a basis of the heat loss due to unburned carbon, expressed in percentage of the heat in the coal.

The relation between percentage of combustible in refuse, ash in coal, and ash-pit loss is given in the series of curves in Fig. 4. These curves are plotted from the formula:

$$\text{Combustible loss} = \frac{100\,ac}{(100-a)(100-c)}$$

where a is the percentage of ash in the coal and c the percentage of combustible in the refuse. This formula is based upon the assumption that all of the ash from the coal goes to the ash pit and that the heating value per pound of combustible in the ash pit is the same as that of the combustible in the coal.

Emphasis is usually placed upon the percentage of combustible in the ashes as being the true measure of loss due to unburned carbon, but it is of equal importance to know the percentage of ash in the coal. There is more heat lost with 20 per cent. combustible in the refuse from a coal with 20 per cent. ash than with 40 per cent. combustible in the refuse from a coal with 8 per cent. ash.

One naturally questions whether the temperature of a bulb at such a location will vary with the percentage of heat lost or with the percentage of combustible in the refuse; whether either relation will hold true for different percentages of ash in the coal, or whether it varies with the boiler rating, grate speed, etc. The final answer to such questions can only be determined from results of actual tests. Fig. 3 is plotted from the 107 samples and it shows conclusively that the temperature varies directly with the percentage of the heat of the coal lost in unburned carbon. Various other plots and studies of the individual tests fail to show any tendency for the results to deviate from this curve due to changes in the percentage of ash in the coal, the grate speed, or the boiler rating.

This is very fortunate, as the temperature record can then be used directly in determining the heat loss without the necessity of bothering with percentage of ash in coal or any other modifying factors. In fact, the chart can be graduated direct in percentage of heat lost instead of temperature. Samples of coal and combustible are needed only for making the calibration tests, which should be determined for each type of installation. At least this will be necessary until more data have been obtained regarding location of bulb and the characteristics of different types of stokers, arrangements of water backs, etc., as these are likely to produce a different rate of temperature change as shown later in this paper.

Performance Results from Chain-Grate Stokers.

It is well known that with a chain-grate stoker the ash-pit loss tends to increase as the excess air is decreased, and vice versa. It is only natural that more coal should be wasted over the end of the grate when the fuel bed is kept thicker and carried to the water back. When the fire burns short a reduction is made in the ash-pit loss, but there is a decided increase in the percentage of excess air. As a matter of fact this is generally true in all types of stokers, and even in hand firing. That is, a reduction in unburned coal usually means some increase in excess air, so that decreasing one loss increases another.

The problem is then to determine what method of operation will give the lowest total loss, and the ash-pit loss recorder makes it possible to plot out these relations as combustion characteristics of the stoker.

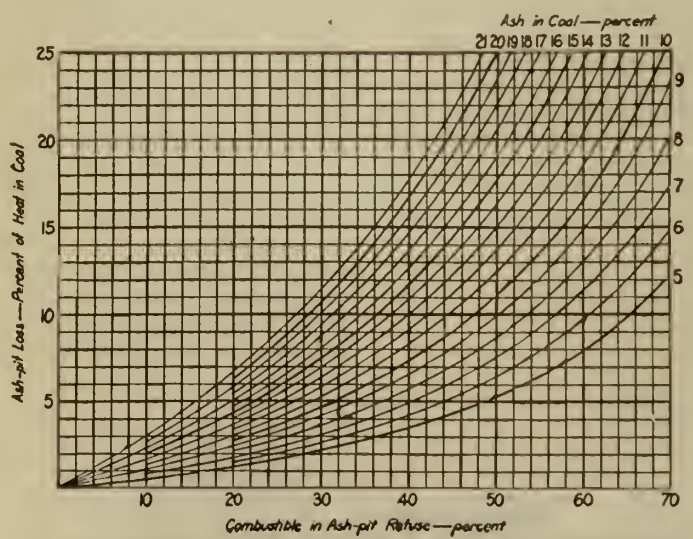

FIG. 4.—RELATION BETWEEN ASH PIT LOSS, COMBUSTIBLE IN REFUSE, AND ASH IN COAL.

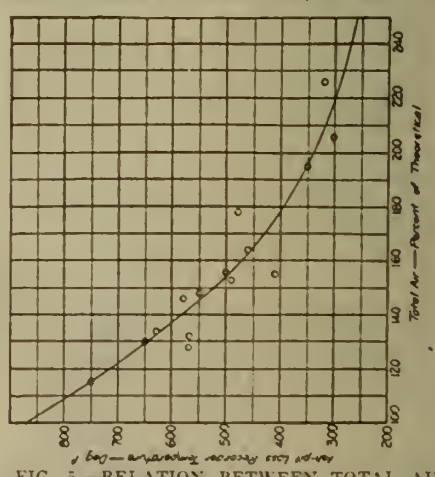

FIG. 5.—RELATION BETWEEN TOTAL AIR USED FOR COMBUSTION AND ASH PIT LOSS RECORDER TEMPERATURE OBTAINED FROM FORCED DRAFT CHAIN GRATE STOKER.

Relation Between Ash-Pit Loss and Total Air Used for Combustion.

Fig. 5 shows a very definite relation between temperature as indicated by the ash-pit loss recorder and the total air used for combustion on a basis of the theoretical air being 100 per cent. In plotting the points the total air was taken from the ratio of air flow to steam flow as shown on chart records, using only periods when the steam flow, the air flow and the ash-pit loss-recorder temperature were each very uniform

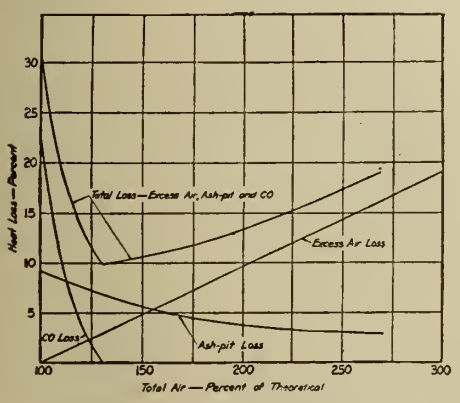

FIG. 6. — CHARACTERISTIC LOSS CURVES ON BASIS OF TOTAL AIR OF FORCED DRAFT CHAIN GRATE STOKER.

over stretches of two hours or more at one time, indicating that the conditions had settled to normal and were not varying continuously.

The values taken from the average curve of Fig. 5 are used to calculate the heat losses and are plotted in Fig. 6, showing the characteristic loss curves for a forced draft chain-grate stoker as operated in Station A. This set of curves shows that percentage of heat lost in excess of air (based on a 500-deg. temperature rise) increases from zero up to 19 per cent. at 300 per cent. total air. As the excess-air loss is reduced the ash-pit loss increases, but the rate of increase is less than the rate of decrease in the excess-air loss, so that the total of these losses decreases until the total air is about 130 per cent. At this point CO and unburned gases appear, and the percentage of heat lost in consequence increases very rapidly as the amount of air is reduced to 100 per cent. or the theoretical amount. It is therefore best to operate this stoker at about 130 to 140 per cent. total air.

It is quite possible that, with a little better care upon the part of the fireman, the combustible loss could be considerably reduced on this type of stoker, even at this low percentage of excess air. This would then lower the total curves so that the combined loss would be still lower than the 10 per cent. shown in Fig. 6 as the minimum point.

Relation Between Capacity and Stoker Losses.

Fig. 7 shows the relations between the boiler rating and flue-gas temperature, excess air, unburned combustible, and CO, with the percentage of heat lost in each. The total of these three losses is seen to be at a minimum of 11 per cent. at 225 per cent. rating and to remain below 12 per cent. at all ratings between 160 and 260 per cent.

The minimum loss in Fig. 6 is 10 per cent. because the excess-air loss is calculated on the arbitrary bases of 500 deg. Fahr. rise in flue-gas temperature, while in Fig. 7 it is calculated on the actual temperature, which is as high as 650 deg. at the higher rating.

If it were possible to operate this stoker with lower excess air at the lower ratings and lower ash-pit loss at the higher ratings, the total losses would be materially decreased and the curve would be flatter. In fact, the range of best efficiency as shown in Fig. 6 should be almost entirely independent of boiler rating if the same care is exercised by the fireman at the low ratings as he must exercise at the high ratings to produce the steam.

To obtain the total overall efficiency curves for stoker, furnace, boiler, and perhaps economiser, the other losses due to products of combustion and infiltration of air should be included according to the equipment used. There is also the question of overhead charges and repairs to stokers and brickwork that increases with higher rating or lower excess air.

Characteristic Curves of Stokers

This set of curves raises the question, can true characteristic curves be drawn showing the performance of the stoker itself? Very little has been done in this direction, but such data have been well established for centrifugal pumps, motors, turbines, fans and blowers.

In the operation of a stoker so much depends upon the character and quantity of coal being burned and also upon the human element of the fireman that the true characteristics of the stoker are usually so clouded that they do not appear in their true form.

Most boiler tests give combined efficiency of furnace and boiler as it is difficult to separate the two. In reality it is not necessary to separate these two efficiencies or even to determine the efficiencies at all, because a great deal more can be accomplished through studying the losses than can be obtained from knowing the overall efficiency alone. We know that if the losses are high the efficiency is low, and vice versa. It is also easy to separate certain of the losses and charge them directly to the furnace, while other losses may be chargeable entirely to the boiler and still others are beyond the control of either.

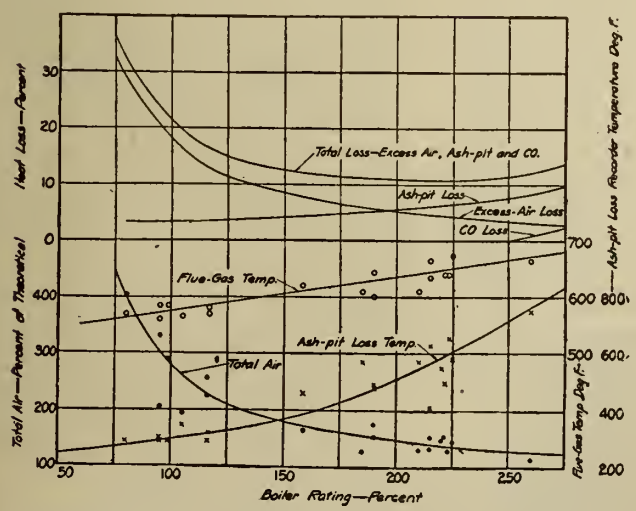

FIG. 7.—CHARACTERISTIC LOSS CURVES ON BASIS OF BOILER RATING, OF FORCED DRAFT CHAIN GRATE STOKER.

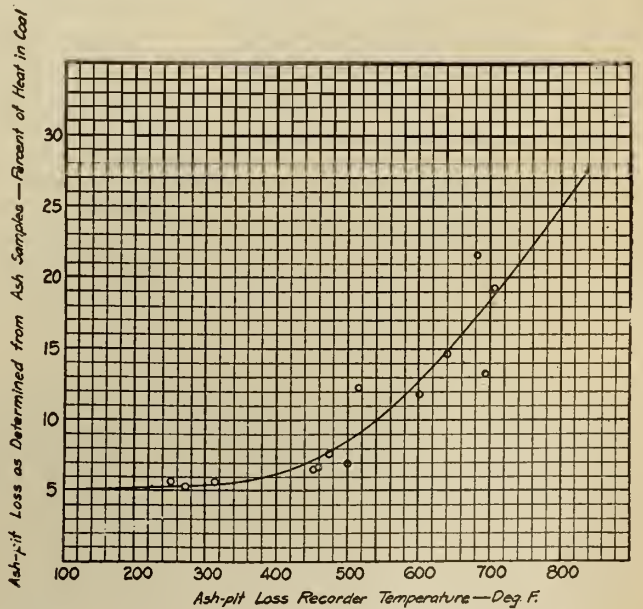

FIG. 8.—ASH PIT LOSS AND TEMPERATURE RELATION, BULB AS IN FIG. 1—NATURAL DRAFT CHAIN GRATE STOKER.

The three important losses existing in boiler and furnace operation that are chargeable directly to the stoker and furnace are unburned combustible in ashes, unburned gas, and excess air. The latter two losses may be influenced somewhat by the size of the furnace and com-

bustion chamber, and the last one by the leakage of air through the boiler setting, but on the whole they depend almost entirely upon the stoker and its operation.

If the characteristics of the stoker are properly determined one can then see the best relation between these factors in order that the total of the three losses be a minimum. We are then assured the furnace efficiency is highest even though we may not know the exact thermal efficiency of the furnace and stoker itself, separate from the boiler.

In operating stokers it has been considered that the character of the coal and the method of operation were far more important than the characteristics of the stoker itself. This, however, is only an admission that the stoker was not so designed that its characteristics would dominate over the other factors, namely, coal and fireman. Very great improvements have been made in stoker design and methods of operation, but there is need for still further advancement. A careful analysis of the problem by means of continuous graphic records of all the losses and characteristic performance curves like those shown in Figs. 6 and 7 will aid in further improvements in both design and operation as well as in selecting coal for the stoker or the selection of a stoker for the coal available.

Even where ash-pit loss recorders cannot now be easily applied to some types of stokers it is possible to take hourly samples of the refuse and plot the characteristic combustion and capacity curves like those in Figs. 6 and 7. For stokers with intermittent ash dumps the period for each test should be the same as the period between dumps, maintaining the operating conditions as uniform as possible during this period and taking the ash sample from each dump. As the value of these results does not depend upon coal weights and evaporation efficiencies, short tests are satisfactory for determining the losses due to excess air, unburned gas and unburned coal. All of the losses of the boiler heat balance, except radiation, can be determined almost if not quite as accurately as can be the evaporation.

diant heat. As soon as a few pieces of hot coke are carried over, the effect upon the bulb is very markd and a considerable rise in temperature takes place until the grate is covered with coke. A greater amount of combustible will add only to the thickness of the layer and not increase the area of the hot coke within the vision of the bulb in this location. The increase in the temperature of the bulb is due only to the closer proximity of the hot coke to it after the grate is once covered.

In Fig. 9 the relation plotted between total air and ash-pit loss-recorder temperature shows widely scattered points. This is largely because the fuel-bed conditions vary rapidly, and there is considerable time lag between the condition of the fuel bed on the grate proper and the amount of coke being discharged at the same time. The log, Fig. 12, plotted over a short period, shows a typical case of the variations as the fire burns thin and is again thickened. The ash-pit loss-recorder temperature drops with the short fire, but the lowest temperature is not reached until twenty minutes after the greatest air excess and the lowest steam flow.

The conditions of the fuel bed on this stoker are sometimes very good and sometimes very poor, just as it may happen, due either to the stoker characteristics, the human factor, or the coal factor, or to a combination of all three. In any case there are certain average conditions which tend to repeat and show the relationship between the various factors. It is very evident from Fig. 9 that very high excess-air and high ash-pit losses do not occur at the same time, although either may be low when the other is high, but they should both be low for the best efficiency.

In Fig. 10 it will be noted that the natural-draft chain-grate stoker in question, as it was being operated at this time, gives the best efficiency at about 210 per cent. total air, with a loss of 18 per cent. due to excess air and unburned coal. We all know that better results than this can be obtained under suitable load conditions with good operation and the right kind of coal, yet these curves indicate that there is a tendency for the losses to increase very

Results from Natural-Draft Chain-Grate Stoker at Station B.

Figs 8 to 12 give the data from thirteen ash samples and tests on a natural-draft chain-grate stoker equipped with an ash-pit loss recorder as shown in Fig. 1. These data were obtained on three consecutive days from a boiler that was being operated in a stand-by station. The load conditions did not require careful attention to the stoker operation, hence the results should not be taken as indicative of the best performance with this type of stoker. Neither should these results be used for comparing one type of stoker with another, because the operating factors, namely, coal and fireman, may be very different.

In Fig. 8 the ash-pit loss increases very slowly with the initial rise in temperature and then more rapidly at the higher temperatures. Referring to Fig. 1, it will be seen that the bulb is located at a different position with respect to the fuel bed than in Station A. In this case the bulb is directly over the end of the grate, and looks down upon the coke as it passes beneath it. With a very short fire the coke may "go out" or cease to burn before it reaches the water back and yet contain a considerable percentage of combustible, hence the minimum loss of 5 per cent, with little or no ra-

rapidly as the fire changes to a shorter or longer condition from the most economical point.

The air having free and equal access to all parts of the grate takes the path of least resistance through the fuel bed and develops holes very rapidly when once started. In many plants the boilers are operated with the damper wide open. If the maximum amount of steam is not needed the fire burns short. If more steam is needed the stoker is speeded up and a little greater proportion of the grate area is covered with active fuel bed. In other words, the steam pressure is regulated by means of excess air. Fig. 12 shows this very nicely, as the air flow remains practically constant and more or less steam is produced as the coal is fed into the path of the air.

Fig. 11 shows the excess-air and ash-pit losses plotted on a basis of boiler

rating. The total of these two losses has its lowest value of 18 per cent. at about 90 per cent. rating. At lower ratings the excess-air loss increases rapidly and at higher ratings the unburned coal loss increases even more rapidly.

One naturally wonders whether the ash-pit loss would continue increasing at the rate indicated by the slope of this curve if the boiler were operated at still higher rating. The limit in this direction is reached when the space under the water back is completely filled with ash and coke. The percentage of combustible lost when operating with the space under the water back completely filled with ash and coke combined, will depend upon the percentage of ash in the coal, the coal-gate opening, and the height of the wafer back above the grate, and will be practically independent of the speed of the grate.

If the increased rate of combustion is obtained by increasing the gate opening and the intensity of draft, leaving the grate speed and the space under the water back constant for a given percentage of ash in the coal, a decrease in the ash-pit loss will result as shown by the upper dotted curve at the right of Fig. 11, because there will then be more ash per square foot of grate and therefore less space left for coke under the water back.

For any given relation between gate openings and space under water back the percentage of combustible lost would decrease with increased percentages of ash in the coal, and should of course remain constant for different ratings. A change in the height of the water back would also have a similar effect, the percentage of ash-pit loss remaining the same for all ratings in both cases so long as the space under the water back was kept completely filled and increased ratings obtained by increasing grate speed.

If the fire burns thinner, the ash-pit loss will be decreased for any of the foregoing conditions and the excess-air loss increased.

It is believed that characteristic curves like those shown in Figs. 10 and 11 will be very helpful in obtaining the best results from natural-draft chain-grate stokers. By means of such curves we should be able to accomplish better results in the arrangement of water backs, regulation of coal gate, grate speed, draft, etc., and also assist the fireman in obtaining the required amount of steam with the minimum loss.

SPLIT BELT PULLEY.

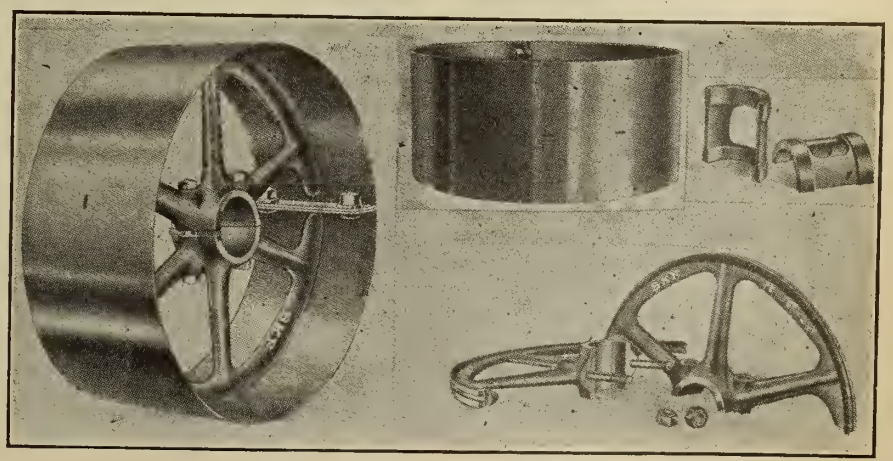
The S. K. F. Co., Ltd., Toronto, Canada, have placed on the market a line of new split belt pulleys which have some special features well worth mentioning. These pulleys are made in sizes from 8 inch to 60 inch diameter, these having a difference of 1 inch up to 24 inches, of 2 inches up to 40 inches, and of 4 inches up to 60 inches diameter.

Reference to the illustration tells the story in itself. As will be noted, the pulley consists of the following parts: A cast iron spyder made in two similar halves is provided with suitable fastening bolts. These halves are machined to receive interchangeable shaft bushes, or S.K.F. ball bearings of the adapter type as necessary. The periphery of the spyder is machined and a groove cut to receive the snugs (as they are called) formed in the rim by press tools, this, of course, preventing lateral movement of the rims. The adjacent ends are notched to locate rim balance weight.

The rim is made from suitable quality steel to withstand high tensile strength, and is finished by cold rolling. The ends are flanged and pierced to receive the two stretching bolts. A balance weight of sheet iron is placed within the rims when assembling, and is located by notches as already mentioned. No shaft keys are required on this style of pulley as they are intended for line shaft drives to machines or main drives to line shafts from electric motors.

The chief feature in this pulley is the interchangeable rim. Its advantage is self apparent, for rims up to 9 inches wide are interchangeable with those of lesser width on the same spyder and bush where necessary. Intermediate drives to line shafts, up to 2½ inch diameter, originally installed for continuous driving, may be converted for intermittent use by the substitution of a wider rim with flat face on the driving pulley, and the addition of a second driven pulley with crowned face, into which may be inserted ball bearings of the adapter type to carry the belt as a loose pulley.

It might be imagined that the adoption of the bushing system without keys would limit the use of these pulleys to light duty drives. However, this is not the case, for the company claims that they recommend with confidence these pulleys for main drives which are reasonably steady, such as those from electric motors to line shafts, driving machines in groups where a main belt is working at 3,000 feet per minute, or more; for instance, a line shaft speed of 250 r.p.m. transmitted through a pulley 48 inch diameter. It is, however, in the case of line and countershaft pulleys, where these pulleys will find their greater scope.



VIEW SHOWING DETAILS, ALSO ASSEMBLED PULLEY.

Using Hydraulic Tests as a Safeguard

Extract from a report to the Manchester Steam Users Association by their chief engineer Mr. C. E. Stromeyer. The author's position in the engineering world makes his statements of great interest.

By C. E. STROMEYER, M. I. C. E.

PROOF testing of completed structures is probably the most primitive method of determining their safety, and is still looked upon by the public, as reflected in the official mind, as the only safe method. Engineers, however, have long ago been dubious about its value, and prefer to rely on experiences which have gradually become sufficiently well defined to constitute a science. This Association has in a certain sense been a pioneer in throwing doubt on the infallibility of hydraulic testing of boilers, for it was founded for the purpose of demonstrating that boiler explosions could be prevented by thorough internal inspections, and it has been our practice to refuse to sanction the application of hydraulic tests to boilers before their strengths have been calculated; and no hydraulic test is considered complete unless it has been followed by an internal examination. Such examinations have frequently revealed fractures of stays and other parts, which had either been caused by the hydraulic tests, or, at any rate, had not been revealed by them. Quite recently a nearly inaccessible locoportable boiler was satisfactorily (sic) tested by hydraulic pressure without bulgings or other signs of weakness, yet on examining the boiler after the test, as far as this could be done through small hand holes, it was found that the three steam space stays, 1¼ inch diameter, had been broken off at both ends. A subsequent examination of these stays shewed that their material was bad.

The question may well be asked: Do hydraulic tests of vessels which cannot be examined internally offer any security against explosions? In attempting to answer this question we have to bear in mind the nature of inaccessible vessels subjected to steam pressures.

We have, first, a number of types of steam boilers which are too small and too complicated to be examined internally. Nearly all road locomotives belong to this class. Then there are steam pipe ranges. These pipes cannot be examined internally after erection. Cast-iron sectional boilers and many cooking vessels, drying cylinders, and chemical retorts are as a rule inaccessible for internal examination. Assuming that any of these vessels were so weak that they were on the verge of exploding at ordinary working pressures, then a hydraulic test would no doubt effect a rupture if it exceeded the working pressure, and although the damage to the vessel would be the same as if it had been caused by steam pressure, surrounding property would not suffer. In such cases hydraulic tests would be useful in definitely condemning vessels which, without such a test, might have been utilised for a lower pressure, but how are such cases to be selected without inspection? and, if selected and condemned, there should, of course, be no need for an hydraulic test.

Consider the case of a vessel which is subjected to fluctuating pressures, for instance a steam engine cylinder with its millions of changes of pressure per annum, or a steam pipe in which the pressure is turned on and off once a day. In either case fracture will ultimately occur if the intensities of the fluctuating stresses exceed the fatigue limit of the material. Suppose that these excess stresses amount to about 2 tons per square inch, then according to the law of fatigue we may expect failure after about one million revolutions. If these excess stresses were four tons, the life would be reduced to one sixteenth of a million. The higher the designed excess stress over the fatigue limit, the greater would be the fatigue effect of adding 50 or even 100 per cent. to it by means of hydraulic tests, and in a very rough sort of way it may be said that hydraulic tests do as much harm as thousands, or sometimes, tens of thousands of repetitions of working pressures. In fact, if by chance, and because of inability to calculate local stresses of complicated structures, these should exceed the fatigue limit by about 100 per cent., just about the level of the ordinary elastic limit, then, although the structure would stand about 50,000 repetitions of this rather severe stress, it would fail, or nearly fail, under a single application of the hydraulic test. Is it at all desirable that any vessel should have its life either cut short in this manner, or have it reduced by a large percentage every time that a hydraulic test is applied?

There is yet another aspect of this question. Probably all materials have ageing qualities. Badly annealed glass cracks after a time, due to a slow weakening of the material, associated with an increasing brittleness, or rather hardness, old glass being capable of blunting the edges of diamonds. Brass, and especially nickel alloys, change with time; so do the alloys of fusible plugs, and our experiments on a number of samples of steel have shewn that they age fairly rapidly. In good steels this ageing does not seem to affect the strength, but bad steels unquestionably deteriorate with time. Amongst these, Bessemer Steels are the best known example, and whenever they have been used for plates, first by Sir E.J.Reed in warships, the experience has always been the same—that such plates lend themselves to severe workshop treatment as long as they are new, but crack spontaneously some time after they have been riveted up. Hydraulic tests should reveal materials possessing treacherous quality, and have done so on occasion—witness the boilers of the Russian Yacht "Livadia"—but there are a far larger number of undetected cases, for instance the s.s. "Pahud" and her sister ship; and, at any rate, if they have passed the maker's hydraulic test, the chances are that subsequent annual tests would merely fatigue the rapidly ageing material and thus bring about an explosion at an earlier date than would otherwise have been the case. The possibility of such happenings is demonstrated by the occurrence, in countries, like Russia, where official annual hydraulic tests are carried out, of explosions and failures under tests of apparently safe boilers. The disastrous explosion of a dished end of a water tube boiler at Abo, in Finland, in 1917 wrecked the whole power station and stopped the industries of the whole town. The boiler had been satisfactorily tested (sic) three weeks before the explosion, and it is only too probable that this last test had extended an existing small crack till it reached to within one-twelfth of an inch of the outer surface of the one-inch plate. It is positively wicked to apply testing procedures which reduce originally low factors of safety to one-twelfth. The actual cause of these failures seems to be the use of basic steel made of Bessemer scrap. In England, where this material has not been used to any large extent, only a few shell failures have occurred, and these were due to the concentration of caustic liquors in boilers, whereby the steel was embrittled. In none of these cases was the hydraulic test of much use even after leakages had been discovered while at work. In a recent case these leakages were located by the hydraulic test and stopped by electric welding, and it was only when an adjoining vessel shewed persistent leakage which could not be stopped, that suspicion was aroused and that the first vessel was discovered to

have sustained a serious crack.

The hydraulic test has one merit in the eyes of those who resort to it—they know the official mind can be favourably impressed by the word "test," and that any person responsible for the safety of a boiler who can say that he tested it, has a better chance of escape from censure in case of an accident than he who may have carried out the most painstaking examination. Innumerable instances could be quoted from the Board of Trade reports, of remarks that hydraulic tests would have obviated explosion, while the alternative, that thorough inspections would have been still better safeguards is not mentioned.

Hydraulic tests are unquestionably in great favor amongst manufacturers. They reveal, or should reveal, when applied to new vessels, whether the material is bad, whether the workmanship is bad, and whether the draughtsman has been ignorant or made a mistake. Against this view it may be urged that designers should take more trouble than is customary to study local stresses, that the management should be so perfect that bad workmanship is impossible, and that the material should be effectively tested before use. It is a curious fact that the hulls of ships are not tested. The designer evidently knows his art to perfection, the material is reliable, and the one hundred to two hundred-thousand rivets are all tight, whereas the boiler of such a vessel, with only, perhaps, 2 per cent. of the above number of rivets, is tested. It would seem that the boiler is and the ship is not tested because the one can and the other cannot be tested. Under present conditions, proof tests by the makers or purchasers will, of course, continue to be made, but it must not be expected that they will offer an absolute guarantee of safety. (See first Table.)

There seems to exist a feeling that facts as represented by hydraulic tests cannot lie. Unfortunately they do not speak the whole truth, except in those rare cases where a hydraulic test actually bursts a boiler. This conclusion is arrived at by examining the following tables. The first one contains those cases reported on by the Board of Trade, in which the boiler or other vessel exploded within two years of delivery. In the majority of these cases, fifty in number, the makers will have tested these vessels; nevertheless in 33 years a large number of objects which were of weak design, or defective material or workmanship, survived the test only to explode shortly afterwards.

The second Table is of even greater interest. It contains all those cases reported on by the Board of Trade in which, on account of repairs or of changing hands, hydraulic tests were applied but did not reveal the defects which soon afterwards resulted in explosions. There are fourteen of these cases, most of them very instructive.

TABLE I.

Steam Boilers, Pipes, etc., which failed within two years of delivery. In most cases hydraulic tests will have been applied by the makers. In a few cases these are recorded.

Cast-Iron Steam Pipes and Cylinders

No. 1798—2 months; thin metal; hydraulic test, 200 pounds. No.1982—3 months; flaw in metal. No. 2179—10 days; thin metal. No.2306—39 days; bad casting. No. 690—17 months; thin metal; ⅛ inch. No. 1054—14 months; casting flaw; No. 2392; 9 months; casting flaw; hydraulic test, 300 pounds; 110 pounds working pressure.

Various Cast-Iron Vessels

No. 87—New—Heating table; weak set-screw stays; No. 119—New—Valve chest; thin metal. No. 414—New; flat side of engine; too weak. No. 13—New; De Coudon ironer; bad casting; hydraulic test 120 pounds; working pressure 40 pounds. No. 755—New; ribbed door; too weak. No. 896.—New; heating table; too weak; No. 1350—10 days; super-heater top; too weak. No. 1626—40 days; flat side of water catcher; too weak; No. 2010—2 days; horse-shoe steam dryer; casting flaw. No. 1242—2 years; ribbed door; too weak. No. 1322—12 months; heating table; too weak. No. 1567—2 years; De Coudon ironer; bad casting; No. 1930—17 months; top of feed pump; casting flaw; No. 2074—22 months; flat side of steam trap; too thin. No. 2136—8 months; heating table; too weak. No. 2370—2 years; vulcanizing press; fractured cast-iron stays.

Boiler Shell Plates

No. 265—7 months; longitudinal flaw in shell; No. 482—21 months; circumferential crack in shell; No. 1699—5 months; crack in root of dished end plate.

Various Vessels of Steel and Copper

No. 849—New; copper pipe of water-tube boiler too thin. No. 957—2 months; crack in flanged end of steel pipe; No. 1555—New; copper drying cylinder; defective joint; No. 1758—2 months; pipe weakened by threads at screwed-on flange; No. 124—8 months; cylindrical furnace too weak; hydraulic test 255 pounds; working pressure 120 pounds. No. 619—17 months; Cornish boiler, furnace oval 1½ inch. Hydraulic test 100 pounds; working pressure 25-45 pounds. No. 1201—18 months; defective tube connection in water-tube boilers; No. 1224—17 months; pipe weakened by threads at screwed-on flange. No. 1406—13 months; pipe weakened by threads at screwed-on flange. No. 1736—1 year; copper pipe; defective material. No. 1770—22 months; copper pipe; defective material; No. 1857; 2 years; pipe weakened by thread at screwed-on flange.

Defective Welds

No. 2133—3 weeks; welded shell of jacketed pan; No. 392—3 months; welded flat end plate of cylinder. No. 805—9 months; welded saddle boiler. No. 1237—18 months; welded end of annular boiler; No. 1580—7 months; welded heating boiler. No. 1890—6 months; welded boiling pan. No. 2166—22 months; welded-on flange of steam pipe. No. 2187—11 months; welded boiling pan; hydraulic test 120 lbs. No. 427—2 years; welded cross tube. No. 455—23 months; welded tube of water-tube boiler. No. 1045—12 months; welded steam pipe. No. 1221—2 years; welded tube of water-tube boiler.

TABLE II.

Steam Boilers, Pipes, etc., which failed within two years of being tested by hydraulic pressure.

Cast-Iron Vessels

No. 2039—Sectional water heating boiler, had accidentally been converted into a steam boiler; hydraulic test 100 pounds; burst 4 months later; pressure 7½ pounds. No. 1374—Conical casting, tested to 150 pounds when new, burst 10 months later at 90 pounds pressure. No. 1836—Cast-iron ring riveted to a steel shell; tested to 180 pounds; burst 3 months later at 120 pounds.

Boiler Failures

No. 221—Loco boilers; tested to 140 pounds; burst 2 months later at 133 pounds. No. 1326—Old marine boiler repaired and tested to 140 pounds. Burst 2 months later at 60 pounds. No. 180 Old loco boiler; tested to 70 pounds; burst 17 months later at 50 pounds. thickness 1-32 inch.

Cases of Grooving

No. 201—Old loco boiler; tested to 175 pounds; burst one year later at 120 pounds; thickness 1-64 inch. No. 344—Old loco boiler; tested to 185 pounds; burst 6 weeks later at 115 pounds; thickness 1-32 inch. No. 1493—Horizontal vessel; tested to 65 pounds; burst 2 months later at 45 pounds.

Cases of Extensive Wasting

No. 303—Old loco boiler; tested to 80 pounds; burst 2 months later at 66 pounds; thickness 1-32 inch. No. 607—Loco boiler; tested several times during four years to pressures of 130 to 200 pounds; burst at 60 pounds one month after last test of 130 pounds; thickness 1-8 inch; evidently a case of life being shortened due to fatigue effect of repeated hydraulic tests. No. 844—Old loco boiler; tested to 120 pounds; burst one year later at 42 pounds.

Broken Stays

No. 1370—Old loco boiler; tested to 200 pounds; burst seven months later at 120 pounds.

Wasting of Flat Plates Around Stays

No. 788.—Navy type boiler; tested to 100 pounds; burst 6 months later.

In addition to the above tables the following notes have been prepared for a special purpose, and are here inserted

as being of interest as regards the question of hydraulic testing, because they shew that, even amongst such inaccessible objects as drying cylinders, periodical testing could not have prevented these twenty-nine explosions, except, perhaps, a very doubtful one, No. 2476, in which case the defective internal drain had allowed water to accumulate and the soldered end gave way due to heavy weight in the cylinder. The steam inlet valve was found closed after the accident, so that this case is not really an explosion. The other cases are as follows:—

Nos. 81, 86, 249, 273, 1907, 2041, 2042 2169, 2253, 2255, 2284, 2361, tin plate cylinders, and Nos. 17, 163, 325, 1985, 2154, copper cylinders, failed in consequence of the absence of essential safety appliances. Hydraulic tests would not have prevented these explosions from occurring.

Nos. 652, 892, 1630, 1812, 2223, tin plate cylinders, and No. 2211, copper cylinder, failed on account of being worn out. Here hydraulic tests might have revealed the condition of affairs, but No. 2223 cylinder was repaired and tested to 20 lb. pressure only five weeks before it exploded at a pressure of 10 lb.

Nos. 920, 1140, 1743, tin plate cylinders, and No. 205 copper cylinder failed due to cracks which the respective plumbers had covered with solder. Hydraulic tests would not have revealed these defective repairs.

Nos. 86 and 2253, previously mentioned, revealed, when they failed, very careless workmanship as regards riveting, yet the hydraulic test on these vessels when new gave no indication of these defects. This is quite natural, for these vessels have large margins of safety, for instance, a duplicate of cylinder No. 2253 was tested to 119 lb. without leaking, though its working pressure was only a few pounds.

The above remarks apply with even greater force to cast-iron vessels, which are all designed to have very large factors of safety, which factors have to cover casting strains, wrong casting temperatures and shifting of cores, associated, of course, with local reductions of thicknesses. It may and does happen that a cast-iron pipe of nominally ¾ inch thickness may have been cast with a shifted core, resulting in the metal being say 1-8 inch thick on one side and 1⅜ inch on the other. Now although such a pipe has only one-sixth of its intended strength, and would very soon fail in practice, it would, if the thin metal were sound, be strong enough to pass the hydraulic test of double the working pressure.

IMPROVEMENTS IN COAL MINING

Closer attention to the economics of coal mining was urged by J. J. Rutledge, superintendent of the Central Experiment Station of the United States Bureau of Mines, Urbana, Ill., in an address delivered before the recent meeting of the Illinois Mining Institute. Changes which will reduce the cost of production and increase the amount of coal per unit cost are made necessary by the present condition of the coal market, Mr. Rutledge said.

"Coal is now selling with great difficulty," he said, "I have been told that screenings in Central Illinois are being offered for sale as low as 50 cents per ton, which is certainly far below cost of production. Lump coal does not seem to have suffered as badly as fine coal, but there has been some cutting of prices in this grade also.

"Some of the mines in the Southwest have not worked since last December. Others, railroad owned mines or mines supplying railroad coal exclusively, are only working from two or three days a week. One operator with thirty years' experience in the Southwest district told me he had never seen a condition like the present one. He said there was no market for fine coal, yet he could not help making some fine coal, if he was to make lump coal and the loss he was compelled to suffer on the fine coal would compel him to charge at least $15.00 per ton for his lump coal in order to come out even. One company had 56 'no-bill' cars of fine coal on the tracks and the railroads were refusing to furnish any more cars for the loading of fine coal".

Mr Rutledge urged that there should be some changes in the methods of working coal. Special attention should be paid to greater recovery. In many mines at present worked by the pillar and room system, the maximum recovery varies from 45 to 55 per cent and the remainder of the coal is left in such a condition that it is almost impossible economically to recover it. In others words, Mr. Rutledge said, the coal is irretrievably lost. By improved mining methods, such as panel long wall or pillar and room retreating, the recovery can be increased from 45 to 55 per cent, which is the present extraction, to 80 or 90 per cent, with a considerable reduction in the cost of production.

"If, by the expenditure of an equal amount of entry driving and brushing, from 25 to 35 per cent more coal can be recovered, mining costs can certainly be reduced by adopting the improved methods of mining", he said. "Estimates of the amount that it is possible to reduce the mining cost by improved methods of mining vary from 15 to 25 cents per ton. Moreover, the quality of the coal produced by these methods will be better than that produced by the old method and this will be an additional amount on the right side of the ledger. When our coal is gone, it cannot be replaced and is gone forever. Coal cannot be grown, like wheat, year after year."

Proper scientific study of subsidence would be of great economic importance, Mr. Rutledge said. As an example of the economic importance of such a study, Mr. Rutledge cited an important coal field where the pillar and room method of mining prevails. This field is now producing an amount of coal which has a royalty value of $300 per acre. Under a proper system of mining, involving good recovery, this amount should be increased to at least $500 per acre, the surface and coal being seperately owned. Is it not much better to mine this coal exhaustively and to neglect the value of the surface, when the difference between the coal and surface value is so great? he asked.

Mr. Rutledge also spoke for more rigid inspection of boilers, the use of improved devices for underground haulage to replace the slow, troublesome and expensive animal haulage, and the use of improved mining methods to decrease the necessity for coal washing. He also expressed the belief that underground loading machines will soon be found at work in many coal mines, even as they are now in many metal mines.

"One of the greatest defects in the present system of mining is the loading of slate and rock underground and the transportation of them to the surface to be deposited on the rock dump," he said. "Every car of rock or slate hoisted to the surface at least takes the place of one car of coal and possibly two cars. In other words, if the miners were not loading a car of slate or rock, they probably would be loading it with coal. The driver would be hauling coal, a revenue producing load instead of that which is only an expense and a waste. Moreover, it is necessary to maintain expensive dirt dumps on the surface in order to dump the dirt and this involves an expense. The haulage of heavy slate or rock in mine cars soon destroys them and tends to cause them to be in poor repair at all times. With a good system of mining, such rock or slate would be left underground where it belongs and where it certainly would do more good than on the surface. About the only use such rock or slate is put to after it arrives on the surface is for ballast on highways or railroads.

"Mine accidents and disasters are among the greatest sources of expense in mining coal. Under the dangerous methods of blasting coal off the solid that is followed in some states, fatal accidents to shot-firers are frequent. In one state, where blasting off the solid is almost universally followed, some mines have lost by successive shot-firers' explosions, as many as eight or ten shot-firers, that is to say, any one of several mines have had from eight to ten shot-firers killed in a period of time varying from eight to fifteen years. One mine is said to have actually lost fifteen shot-firers in twenty years of operation; one or two shot-firers having been killed at a time. The average amount paid for a shot-firer's death claim alone, not including damage to the mine and loss of output to the operator and of wages to the miners and other employees, has been from $3,000 to $3,500 each. Several recent shot-firer's explosions have cost

the mining companies concerned amounts varying from $20,000 to $50,000, including damages paid to heirs of deceased shot-firers and repairs to underground workings.

"Surely, it would be cheaper, speaking only from a cold, money-making standpoint, to abolish such a dangerous method of producing coal and endeavor to mine the coal by use of mining machines and permissible explosives."

AN UNUSUAL MODEL

The small photograph attached shows a picture of the Tower Bridge in London, England. The large photograph shows the same bridge made of Crane Valves and Fittings, and it is sent to you with the hope that you may find it sufficiently interesting to publish in your magazine.

This novelty was built at the Bridgeport, Conn. Works of Crane Co., and the only guide used throughout the entire work was the Postal Card view of the original bridge. This bridge is now on display at the Crane Exhibit Rooms, 23 W. 44th. St., New York, and later will be shipped to Crane-Bennett Ltd., London, England.

15358 pieces taken from regular stock, comprising 230 different kinds of Elbows, Tees, Crosses, Nipples, Valves, etc., were used in building the Bridge. 16251 Joints were required to make up the fittings, and it is worthy of note that not one left hand thread was used in the entire structure.

The Bridge is approximately 19 feet long by 11 feet high by 4 feet wide. The spans are 57 inches wide. It is of the Roller Lift Type having four towers, each tower being provided with one elevator. The lifts are 22 inches long by 30 inches wide.

The elevators are 6 inches square by 8 inches high. The upper part of the elevator cage being made by using a Brass Floor Flange with a Plug screwed in, into which the cable used for raising and lowering the elevator is fastened. The men operating the elevator are represented by Reducers, Nipples and Caps.

THE REAL TOWER BRIDGE.

The Towers are neat in construction and well proportioned, having four spires—one on each corner. These spires are neatly constructed by the use of Malleable Iron Reducers, Caps and Cast Iron Flange Unions.

The cables connecting the Towers to the approaches are made up of Nipples, Tees and 45 Degree Elbows.

Each approach is provided with two clocks bearing the name Crane-Bennett, Ltd.

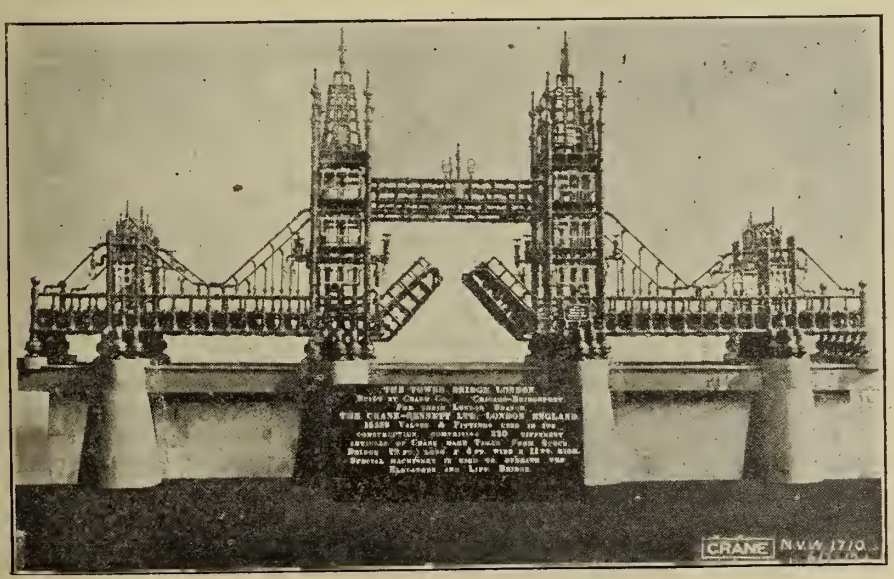
The Lifts and Elevators are raised and lowered by specially devised machinery. The reversing is done by an unusual mechanical movement and no clutches are used in its construction.

The Bridge is illuminated by thirty-six lights, eight being red and green for controlling traffic; four of which are used for navigation and four for traffic on Bridge. When the Bridge is closed the red light flashes and the green light extinguishes to show that the Bridge is closed to navigation. At the same time, the green light open traffic on the Bridge. When the Bridge is open, the green light flashes to navigation and the red light to traffic on the Bridge. 800 feet of wire was used to carry out the electrical effect.

In the sidewalks there are 1600 Right Hand Close Nipples, together with numerous Galvanized Tees, Crosses and Elbows. This has offered a great amount of speculation as to how the Elbows, Tees and Crosses were made up with Standard Right Hand Close Nipples, each fitting being not more than 1/16 inches apart, and is worthy of consideration.

The curb separating the sidewalk from the roadbed is represented by Galvanized Nipples slotted and slipped over a tongue which holds an amber glass roadbed.

The Bridge is mounted on skids covered with Granite Packing painted a wavey green. When looking through the amber glass roadbed onto the green Granite Packing, it gives a very good effect of the witching waves.



MODEL OF TOWER BRIDGE MADE ENTIRELY OF PIPE FITTINGS.

U. S. LIGNITE

Dr. Erich W. Zimmerman, consulting economist of the United States Bureau of Mines, has submitted to Director H. Foster Bain, a preliminary report on the marketability of beneficiated North Dakota lignite. The report analyzes the conditions surrounding and the difficulties affecting the fuel supply of North Dakota, South Dakota and contiguous territory. The ultimate purpose of this study is to provide the necessary economic data upon which an estimate of the commercial possibilities of beneficiated North Dakota lignite may be built up. The report specifically deals with coal production and consumption in the territory mentioned; Northwestern fuel prices; Northwestern fuel imports with special reference to their sources; the Lake coal trade to the Northwest, and the railroads and the Northwestern fuel supply.

Overhauling and Adjusting in the Engine Room

In this article the mechanism of the simplex pump valve is described. The first example chosen is the Darling pump, which is a typical example of this style.

By "FITTER".

THE VALVE motion of a simplex type of pump must necessarily be of a different character to a simple rotary engine or a duplex pump. In the duplex pump we have the two rods, each of which can be employed to operate the valve of its neighbor, and providing continuous motion once the pump is started. With the simplex pump however we have only the one rod, and some means have to be adopted to enable the piston to reverse at the end of its stroke, and in working out the details of this some ingenious motions have been devised. It is our intention in these articles to explain the motions on the better known types of simplex pumps, so that the young engineer and perhaps some of the older ones may become thoroughly acquainted with these various mechanisms.

The arrangement adopted in practically all cases, a combination of two valves, one the main valve which admits steam to the piston, and the other a small valve which is used to admit steam to a piston which works the main valve. This auxiliary valve is worked by the pump rod through a lever, and though the details of ports differ in different makes of pumps the broad principles are the same. The valve gear of a simplex pump may then be summed up as consisting of a lever, driven by a roller attached to the pump rod, with its upper end arranged to move the auxiliary valve spindle, the auxiliary valve and the main valve. A simple arrangement surely, but one that can be very troublesome if it is neglected, as many of our readers probably know by painful experience.

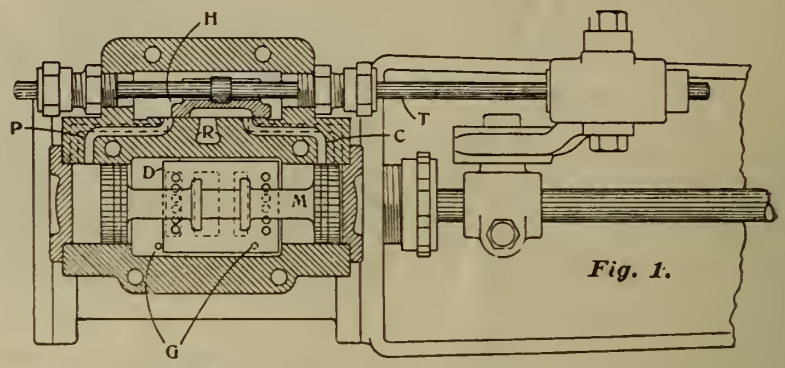


Fig. 1.

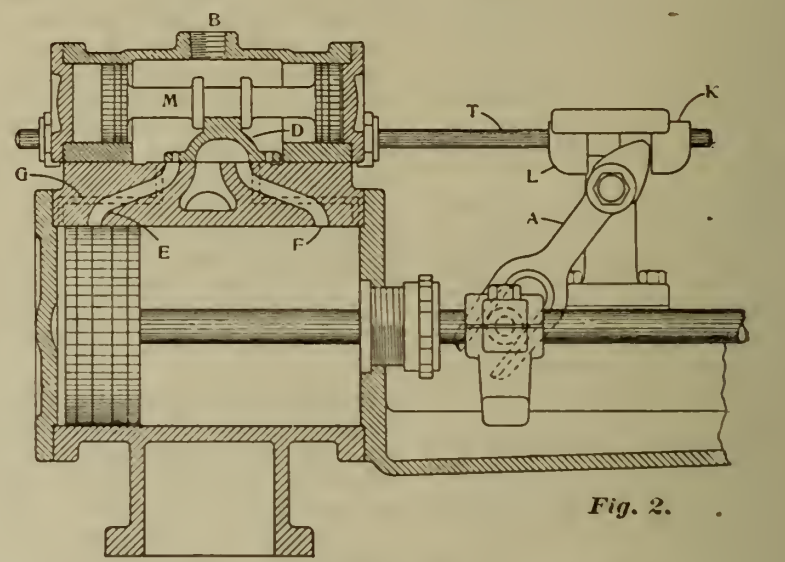

Fig. 2.

SECTIONAL PLAN AND ELEVATION OF VALVE CHESTS.

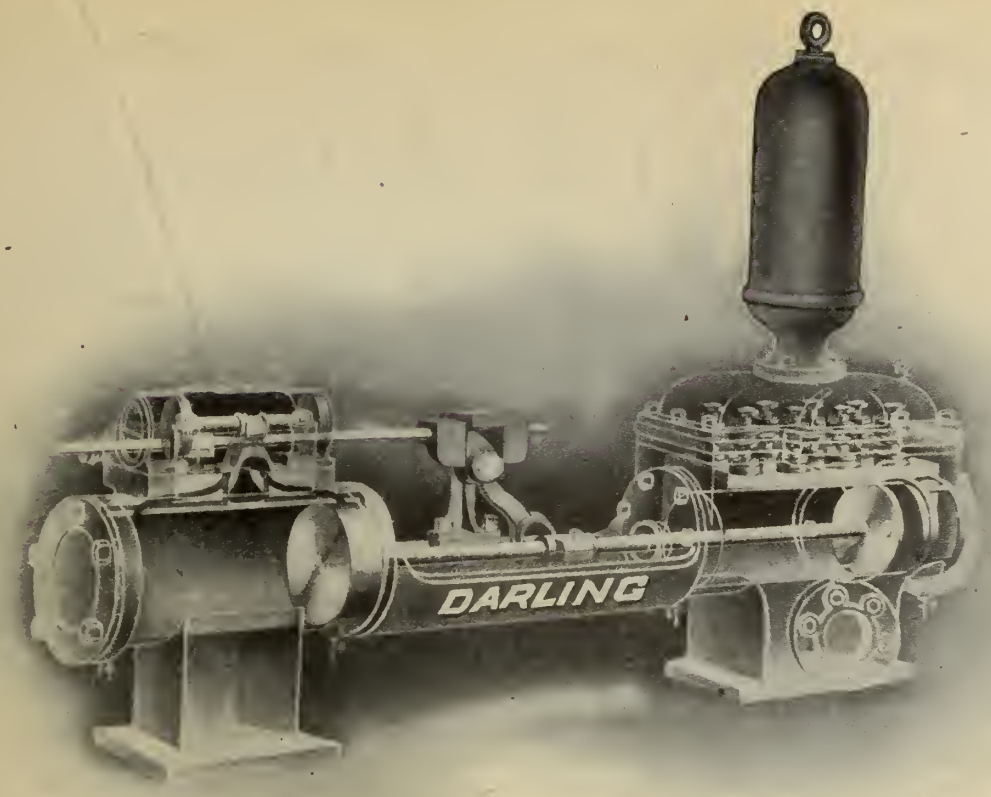
The Darling Pump

The first example we will take is that of the Darling pump, which is a good example of this type, and by following the description and the cuts the operation can be very clearly seen. The top cut Figure 1 is a sectional view looking down on the steam chest, showing the main and auxiliary valves, while the lower cut, Figure 2, shows a vertical section through the pump, the main piston, the main valve, and the valve piston being shown. The various ports can be clearly seen.

Looking at the top cut, we see that the auxiliary valve H is a plain D slide valve, fastened to the valve spindle, which is driven by the lever attached to the frame. The lower end of this lever fits over a roller which is carried by a bracket clamped on the pump rod, and as the end of the lever which drives the valve spindle is above the fulcrum, the valve spindle is moved in an opposite direction to the piston rod when the pump is working. The auxiliary valve has live steam on the outside and the cavity communicates with the exhaust in the usual manner. Its function is merely to move the piston to which is attached the main valve D. The two lugs L and K on the valve spindle are made adjustable, so that the instant when the auxiliary valve will be reversed can be varied by the engineer, thus making the stroke of the pump slightly longer or shorter according to necessity. Perhaps we should say giving a little more or less cushioning rather than a shorter or longer stroke.

Looking at the top cut again, we see there are two ports in the auxiliary valve chamber, P and C and these communicate with the ends of the main valve driving piston. Shown in dotted lines are two other ports, behind the first two, and extending to the extreme end of the casing in which the piston works. The object of these two ports is to supply a small amount of steam at the very beginning of the stroke of the piston, so that it will start up gradually, and have moved a little way before it gets the full amount of steam from the main port. In the position shown in the cut, the piston of the pump, or the main piston, has just reached the end of its stroke at the outer end of the cylinder. The lever has moved the auxiliary valve spindle to the outer end of its stroke and the auxiliary valve has thus given steam through the port P to move the main valve piston over to the front end of its stroke. In doing this the main valve D has also moved over to the right and is now open to give steam through port E to move the piston back to the other end of the stroke. However, as we see in the lower cut, this port E is blocked by the piston, so that no steam can reach it while in that position. There is behind the main port, and shown in dotted lines an auxiliary port G, and this port is open to the small clearance space behind the piston. Thus there is available a small amount of steam to start the piston on its stroke, and start the water in motion slowly until the piston uncovers the main port, when it will gradually come up to speed. Thus there is no sudden shock and lifting of valves when the stroke is started.

Now let us follow the piston to the other end of its stroke. As it moves forward carrying the lever with it, the lever will gradually straighten up, the valve spindle remaining stationary, until half



PHANTOM DRAWING OF PUMP

stroke is reached. After that the lever will swing towards the block L, until as the rod reaches the end of its stroke the auxiliary valve spindle will be moved over to the left and the main valve also thrown over ready to give steam to the opposite side of the piston.

While the piston has been advancing, the port F has been open to exhaust, and will remain so until the advancing piston covers it. There is then a certain amount of steam in the cylinder, and this being trapped, will form a cushion for the piston, bringing it gradually to rest. It cannot escape through the auxiliary port as that is covered by the main valve. Thus the piston comes to rest and starts from rest very slowly and evenly, and this greatly helps the life of the valves, joints, etc. by doing away with shock and the vibration attending thereto. The effect of altering the position of the lugs K and L will be apparent from the foregoing description. If they are brought close together, the lever will have a smaller arc to travel through before moving the valve, and thus the valve will be reversed at an earlier portion of the stroke thus making the stroke shorter. This will also mean that instead of the piston being brought to rest by the compression of the steam in the cylinder, the valve will open to steam before the end of the stroke is reached and the clearance space will be partially filled with live steam, thus causing a loss. On the other hand if the lugs are separated, the pump will have to reach the extreme end of the stroke before the valve is moved, thus tending to sluggish working, and in extreme cases, to complete stoppage. Somewhere between these extreme positions is the correct position for the lugs to be secured to the spindle, and this can be found without much trouble.

When the pump is at half stroke and the lever vertical, the lugs are set an equal distance on each side of the lever. The pump is then started, and the lugs adjusted until the pump is working with the full length of stroke and without any shock or jerk. There is really nothing to go wrong with this gear, and cases of pumps sticking can be traced usually to a lack of lubrication, too tight packing, or too wide adjustment of the lugs. Of course, the wear on the roller should be noted, and when necessary a new one put in, as if there is much slack on the roller, or on the lever end between the lugs the pump won't function properly. There is another word of warning which is perhaps very necessary to some men. If you have one of these pumps and it sticks, don't resort to banging the valve spindle or the end of the chest with a hammer. Of course it very often succeeds in starting the pump, but on the other hand if the valve was clean and sufficiently lubricated it would not need any persuading with a hammer. Besides if any one were looking through the plant and saw a pump, with the valve spindle and valve chest covers bearing the marks of hammer blows, they would at once conclude that the man in charge wasn't much of an engineer. The valves don't need smothering with oil, but they do need an occasional overhaul and cleaning, and perhaps a little facing up, at which time a good dose of oil will help them to get a surface after starting up again. Too much oil is as bad as too little, it usually becoming a hard greasy mass. The valves will wear a good clean hard surface for themselves, and there is usually enough moisture in the steam to provide lubrication. As in every other thing in the engine room, intelligent care will eliminate trouble, and there is nothing at all in the valve gear itself to cause one moment's worry. It is well designed and as simple as such a gear can be made.

PETROLEUM STANDARDISATION

The Technical Committee on Standardisation of Petroleum Specifications plans an open meeting in the offices of the United States Bureau of Mines in Washington, Tuesday, July 12, at 10.00 a.m. eastern standard time, for the consideration of suggested modifications and additions to Bulletin 5, which contains the specifications under which governmental purchases of gasoline, kerosene, fuel and lubricating oils are made.

From the standpoint of the oil trade the most important change proposed is the addition of a corrosion test to the specifications for motor gasoline. Some of the gasoline recently purchased has been found to be corrosive, and a test has been proposed to insure against a repetition of the trouble.

A few new specifications to cover products not now listed in Bulletin 5 have been suggested. Other modifications have been proposed, looking to improvement in the manner of making some of the tests.

The C. A. S. E. Convention

THE CONVENTION of the Canadian Association of Stationary Engineers just concluded at Ottawa, and fully described in another portion of this issue, was a very great success, both for the members of the Association and the representatives of the various supply firms who comprise the Exhibitor's Association.

The exhibition itself was much more complete than in former years, and was the finest kind of illustration of the progress of power plant engineering. Mr. C. B. Turner who had worked very hard for the success of the event, claimed that not even at the Toronto exhibition could such a complete survey of power plant apparatus be made. We are inclined to agree with him in this, and we believe that these exhibitions and conventions are the finest possible medium for awaking the interest of the general public to obtain a closer understanding and acquaintance with a branch of engineering that lends so much to their daily comfort. It is a good place for the manufacturer also to get a line on the developments that have been made towards the economic running of his power plant, and it would be encouraging to see more of this class of visitors at the conventions. Every manufacturer is looking for cheap power, but we venture to state that a good many of them could get cheaper power if they were to keep in closer touch with their engineer, and get acquainted with some of the modern apparatus, which placed under his intelligent care, would help him to the desired goal.

The President and officers of Ottawa Lodge are to be congratulated on their efforts towards the success of the convention, which were ably backed by the President and officers of the Exhibitor's Association, and between them they succeeded in making the convention one that will be long remembered, by all those who had the privilege of attending.

The Hydraulic Test

MR. C. E. STROMEYER, the Chief Engineer of the Manchester Steam Users Association, and a very widely known authority on the subject of steam boilers, has some interesting things to say in his annual report on the subject of steam boilers. Mr.Stromeyer states without any equivocation that the hydraulic test is responsible for a large number of boiler explosions, and that "it is positively wicked to apply testing procedures which reduce originally low factors of safety to one twelfth."

This statement coming from a man with the authority of Mr. C. E. Stromeyer should make some of our wiseacres pause. In this country it is an unfortunate fact that the hydraulic test is looked upon as a sort of unfailing oracle, that cannot lie. Experience has shown that it can lie, and lie disastrously. Mr. Stromeyer has something else to say which contains a great deal of truth, and these are his words:—"The hydraulic test has one merit in the eyes of those who resort to it:—they know the official mind can be favorably impressed by the word test, and that any person responsible for the safety of a boiler who can say he tested it, has a better chance of escape from censure in case of an accident than he who may have carried out the most painstaking examination."

We have taken the opportunity on former occasions to bring this viewpoint before our readers as we have had a good deal of experience among men who thought that the hydraulic test was the be all and end all of boiler inspection. These men in a good many cases occupied important official positions where their view point had a great deal of influence with those they came in contact with. We know of cases of boiler explosions in this country which we believe could be traced to the hydraulic test as the fundamental cause, and we know that the hydraulic test is being conducted to absurd limits every day all over Canada. Of course it is not only in Canada that this takes place, as the hydraulic test is insisted on by the British Board of Trade, which has a very wide experience in boiler construction and rules, but they limit their pressure to one and a half times the working pressure of the boiler, and make careful inspection before determining that working pressure. The great danger is that some men, possessing that little knowledge that is a dangerous thing, use the hydraulic test as a means of determining the working pressure. The danger of such a course must be apparent.

We are publishing in full that part of Mr. Stromeyer's report which deals with hydraulic testing, and would earnestly recommend its perusal by all those who have any interest in steam boilers, whether they are engineers, inspectors or owners.

Cutting Generators In and Out of Operation

Turbine Running—Putting Generator on Line—Changing Over Machines—Phasing—Changing The Voltage Regulations—Changing Over to Standby Central Station Service—Cutting In Generators.

By J. A. McGillivray.

THIS article is intended to help the operator in small isolated power plants to master the important details of putting machines into and out of service and the operation of switch boards. Where possible, these instructions should be supplemented by personal instruction and practice, under a practical power plant operator. For convenience we will assume that a plant is already equipped and ready for operation, and so as to cover the subject pretty thoroughly let us assume that the equipment consists of the following:

2-Steam turbine driven 3 phase A. C. generators having direct connected compound exciters, with a separate steam driven exciter, compound.

2-Synchronous motor generators or converters.

2-Automatic A. C. voltage regulators. The switch board equipped with Power Factor Meter, Frequency Meter, etc. Oil switches handthrown. A duplicate set of Main Generator busses. Duplicate outgoing feeder circuits. 2-Step up transformers for power distribution. 2-Step down transformers for lighting.

A standby A. C. and D C. connection from Central Station service. The plant is to run continuously without interruption to local service, 24 hours a day and 7 days a week. There is to be kept in reserve one set of everything. The standby service to be used only in case of accident to steam mains or boilers, or other emergency. The change from isolated station service to central service is to be made without interruption to local operation.

"Turbine Running," Putting Generator on Line.

Building Up.—If T. R. positions are not already marked on the rheostats, proceed as follows: Note the range of the voltage regulator, let us suppose that it is from 70 to 140 volts, that is when the regulator is connected across the exciter shunt field resistance. The exciter voltage is automatically controlled between those limits when the rheostat is turned in to a point where the voltage by hand regulation would be 70 volts. (If the rheostat is cut in to a point where the exciter voltage by hand regulation would be 80 volts it would reduce the range of the regulator, that is, the regulation would be automatic between the limits of 80 and 140 volts.) Let us then assume that the point to which the exciter shunt field rheostat is turned, when there is no load on the exciter and the exciter voltage is 70 volts is the correct T. R. position. Mark it. Now you may connect the exciter to the exciter busses having all other switches on the board open. Next close main A. C. generator field switch and build up A. C. voltage to normal using A. C. field rheo, with the exciter shunt field rheo in T. R. position. The position of the main generator field rheo is T. R. position when A. C. generator voltage is normal, mark it. You may now close the main generator switch. (We may call the units (1) and (2) for convenience).

Putting Regulator in Service.

1st.—Close D. C. magnet single pole switch. This energizes the D. C. magnet; now move the exciter shunt field rheostat until the short-circuiting contacts just open or vibrate and close the single pole switches corresponding to No. 1 machine.

2nd.—Check the operation of regulator by gradually cutting OUT main generator field rheo, and note that the main generator voltage remains constant or nearly so. Cut out gradually until the exciter voltage is increased automatically over the full range of the regulator, or until the main generator field rheo is entirely cut out. If the regulation is not good over the entire range refer to the instructions given with the regulator. But it might be well to bear this in mind. The average station operator has no business to attempt adjustments farther than dash pot adjustment and counter-weight adjustments, as the regulator is a delicate instrument and not to be monkeyed with unless he possesses more than average knowledge of its principles. The connections should be gone over carefully as most of the regulator troubles are due to the following causes:

1st. Wrong T. R. position.
2nd. Dash pot too free or dampened too much.
3rd. Commutator trouble.
4th. Bad contacts.
5th. Wrong connections.
6th. Wrong adjustments of magnet cores.
7th. Wrong spring adjustments.
8th. Insufficient condenser capacity, causing arcing at contacts.
9th. Line drop compensating connections not properly made.

The first four are easily and safely investigated by any operator. The others require expert attention.

While the automatic regulator may be said to be a delicate instrument, once properly adjusted it is the most reliable and permanent instrument in the Power Station. The only attention it requires is to renew the contacts from time to time and keep the oil in the dash pot about ⅛-inch from the top, and to throw the reversing switches at least once every watch.

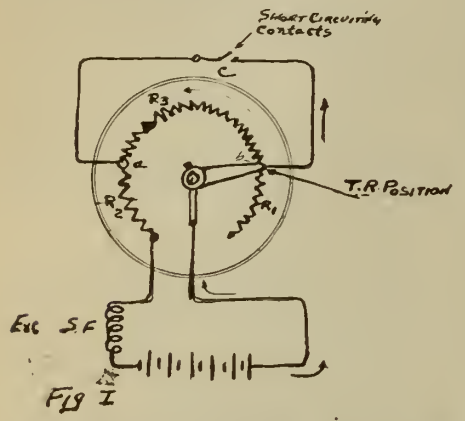
3rd.—Close whatever feeder circuits are required and close the secondary transformer switches. Then the Primarys close whatever lighting switches that may be needed.

4th.—Start the motor generator or rotary. If self-starting type close the starting switch, which is simply a compensator like that on any ordinary motor. Be sure the motor generator field is open before attempting to start. If the field switch happens to be closed even though the rheo be cut in there will usually be sufficient field current to build up a field of sufficient strength to prevent the motor from starting. At the same time there will be sufficient starting current admitted to overheat the windings in a few moments, and probably break the insulation down. When the motor generator is coming to synchronous speed you will observe the amperage falling off gradually and steadily to a point where it no longer falls off steadily, but swings up and down across the scale. Now close the field switch cutting out a small amount of resistance until the ammeter shows no reading. (The time required to do all this is from one-half a minute to one and one-half minutes, depending on the size of the machine and the period required to bring it into synchronous speed).

Next take the starting switch in one hand, the running switch in the other, disconnect the starting switch and instantly close the running switch. It's easy to do with practice. Should you fail to get the running switch closed at the first attempt, do not try it a second time, as the interval of time will be sufficient to let the motor fall out of synchronism and should the main or running switch be closed the generator tends to pull the synchronous motor into step or synchronism instantly with all the available energy of the prime mover behind it, a great surge of current is sent through the motor causing the squirrel cage starting coils to become distorted and fouling the stationary element probably destroying the machine. Therefore, if you fail in the first attempt, start all over again with the starting switch. A synchronous motor is really an alternator and while there are various methods of synchronizing or bringing to speed it is important that the operator bear in mind that he is not simply starting a motor, but is par

alleling two alternatives, which will be explained later on.

5th.—Having the synchronous motor generator in the line the next operation is to put the D. C. end in service. First cut in all the resistance in D. C. shunt field and close field switch, bring voltage to normal, close circuit breaker, then the main switch, close feeder circuit breaker and feeder switches and adjust voltage as load comes on.



While these instructions require considerable time to write them and will require some time to study them, the operations outlined "with the exception of marking the rheostats" can be executed by an experienced operator in from 3 to 5 minutes, but the beginner had better go slow at first.

Now, apart from operation there is no more worry until it is time for the operator to change over machines, without interruption to service.

Changing Over Machines.

First.—Paralleling Exciters. If the station load is not too variable it will be most convenient to parallel the exciters without the voltage regulator in service, since the function of voltage regulation is performed by automatic short circuiting of the exciter shunt field resistance. Thus increasing the exciter voltage to pass a larger current through the alternator field, "the resistance of which is constant," and vice versa. The understanding of this principle stumps most operators, but once they get the idea the rest is easy or comparatively easy to understand.

A reference to Fig. 1 may illustrate the principle in a simple way. The condensers are not indicated but their function will be described.

Let Fig. 1 be a closed circuit with external resistance R. Let a shunt be connected across points a. b. and the resistance R divided into three parts in series R-1, R-2, R-3. If the rheo is turned in to point b, which is T. R. position R-1 and R-2 are constant factors, R-3 is cut in when contact c. is open, and cut out when contact c. is closed. Now let it be for example that the load requirements are such that at any instant the resistances required are (R-2 +½R-3) then if contact c. is closed half of the time and open half of the time we have the equivalent of R-2+(R3-2) having established this fact clearly in your mind you may proceed to study up the regulator and you will have little difficulty. The contact points (c.) could not last a great while no matter what they were made of owing to the arc that accompanies the breaking of a closed circuit carrying a current. The function of the condenser is to condense this arc or choke the discharge when the circuit is broken by the opening of the contacts. The contacts are made of platinum, this metal being able to withstand high temperatures.

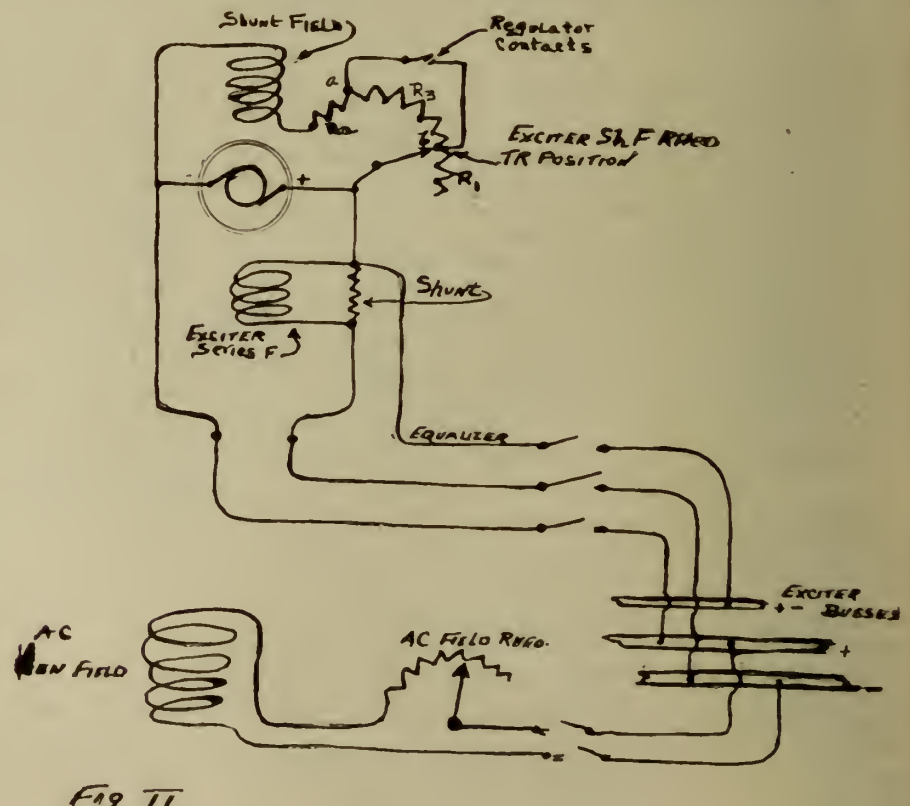
Now as already stated, the regulator may be cut out if the load is fairly constant, or the assistant may regulate the main generator voltage by hand regulation of A. C. field rheostat, while the exciters are being parralleled. The expert operator will, however, parallel the exciters with the voltage regulator in service, thus:

Build up exciter No. 2 a little higher than No. 1, watch the swings of No. 1 voltmeter, when the two voltages are similar close exciter main switch (the switch is usually 3 pole, one pole being the equalizer) when exciter switch is closed, close single pole switches on regulator which correspond to No. 2 machine and set exciter rheo. at T. R. position, then close No. 2 A. C. field switch and build up voltage with the rheostat. Now it may happen that the load on No. 1 machine is so heavy that the exciter buss voltage is sufficient to build up voltage on No. 2 when the rheo. is all in, and this voltage may be in excess of normal, preventing paralleling under those conditions. Where this is a common occurrence the remedy is to insert more resistance in the A. C. field, but until such time as this can be done there is another way out of the difficulty and if very little extra resistance is required it may not be worth while to go to the trouble. This method is to cut out some A. C. resistance out of No. 1 by moving the A. C. rheostat away from T. R. position, thus reducing the voltage at the exciter busses.

When A. C. voltage is about normal try out all three phases of the incoming machine. The voltage across the phases will be or should be the same, and will not necessarily be equal to the line voltage, as this depends on the way the windings are connected, but the voltage must be the same for each of the three phases of all machines that are to run in parallel. Slight unbalancing may be noticed in the loaded machine due to lighting circuits. (See note*).

Note. The installation of small lighting transformers in a plant are sometimes a source of unbalancing as some departments may be using lights while others are not. The amount of unbalancing is rarely important. when it amounts to much balancer sets are installed.

If it is noticed that one phase of the incoming machine is not showing voltage while the voltmeter shows normal voltage some of the fuses in the instruments may be blown, make sure. When this is attended to plug in the synchroscope and proceed to bring No. 2 into synchronism, using the motor control for this, if none installed the engineer must control the turbine governor with hand wheel. The operator will have been told whether to synchronize with dark or bright lamps, if not he mustn't take a chance. He can find out by disconnecting the main generator leads from the oil switch (be sure not to reverse the leads; we assume that the machines have been pha[illegible]) or any convenient place away from it, but between it and the generator. In the gap connect a



temporary 3-pole switch with fuses, say 100 amp. to 200 amp., low enough, of course, not to injure the machine. Now get synchronism with either dark or bright lights and close No. 2 main generator switch at moment of synchronism. If the generator switch can be closed without blowing the fuses that condition is right. If fuses have blown it does not prove conditions are wrong, as the operator may have made a bad throw that is while he may have had synchronous speed the machines may have been out of phase somewhat. It is better to try it a number of times until positively certain.

The difference between paralleling A. C. and D. C. generators is this: In the latter case the only requirement is equal voltage and the same polarity; in the former the requirements are equal speeds. Equal voltage, equal phase angle, or in short synchronism means all of those things. There may be equal voltage and equal speed and still be 180 degrees out of phase at the instant the switch is closed. If the speed of both machines is exactly the same and the machines are out of phase they can never come into phase without a variation in the speed of one or the other.

Since it is the writer's desire to help the operator who is confronted with the problems of operating switchboards as far as possible and to avoid technicalities that serve only to confuse rather than enlighten the average engineer, I will endeavor to explain in a few simple words what is meant by being in phase.

First let me say that it is not really necessary that he, the operator, should know, but that it is nevertheless useful to understand. The understanding of these things may be rungs in the ladder that is to carry him higher in the operating field. There are boys operating switch boards of large stations safely and reliably who do not know the first thing about the phasing out of a generator, all they know is that if they make a bad throw they will hear about it. They are not allowed to do it twice on the same job. They are shown by an expert what to do, they learn it and do it automatically. The fact that they do not realize what it amounts to contributes to their success as operators. They will not be subject to nervousness as they do not worry. A good operator is seldom a careful operator. I do not mean this literally, not only is this true of operators, but in many walks of life, some of the most successful engine drivers and hoist men I ever knew were the most reckless—some of the most unfortunate were the most careful. Some of the readers of this article will remember one of the most careful and conscientious hoisting engineers who ever pulled a throttle, had a great many accidents costing human life, finally broke down mentally, to the genuine sorrow of all who ever met him. A man of fine intellect and great generosity and more than common learning, hundreds of engineers, the writer among them, felt that they lost a personal friend. I would not counsel carelessness, but would warn the engineer against nerves.

Phasing.

The armature windings of a 3-phase generator are connected in 3 groups. From each group a lead is taken to a separate buss bar. Let the groups of coils, their leads and their busses be a., b., c. If another 3-phase generator is to be paralleled with No. 1, the same lead from the same corresponding group must be connected to the same buss bar, etc. Not only must this be so, but the same group in each machine must be cutting the same pole at the same instant and at the same speed of rotation as if fixed on one shaft, one group may not be entering a zone during a cycle while the other is leaving it; in other words, the same coil must be in same position under their respective poles at the same instant.

A cycle is the cutting of a pair of poles, in a two-pole machine a cycle is one revolution and equal to 360 degrees. The phase angle or phase difference will be the difference in the relative positions. Let coil or group a. be at zero degrees of the circle; let the coil or group a. of the machine to be paralleled be a quarter cycle ahead or behind, the phase difference is then said to be 360-4=90 degrees, or 90 degrees apart. The greatest possible disturbance is when an attempt is made to connect the machines when 180 degrees apart, at this value the difference is maximum. To illustrate: If you lay off a circle, take a point on that circle at its circumference, any other point on the circle that is less than 180 degrees is measurably less distant than a point 180 degrees. It is immaterial whether one machine slows up or the other speeds up; the phase difference becomes less.

When positive that everything is in order, the main switch of No. 2 generator is closed at the point of synchronism, the generator A. C. field rheo. is turned to T. R. position and the load is taken over on No. 2 machine by manipulation of the turbine govenor.

When ready to close down No. 1 generator proceed as follows:

Cut in A. C. field resistance in A. C. generator No. 1 again to T. R., change the exciter load over to No. 2 by using the equalizing rheostat. Disconnect No. 1 exciter from the exciter busses and from the regulator. Be sure that you disconnect the single pole switches that correspond to No. 1—there is no hurry. Take your time and watch your moves. Having the exciter clear you may give the engineer the signal to close down. When he does so open main switch No. 1 and immediately cut in all the resistance of A. C. field or there will be a tendency of the voltage on the machine going too high. You may leave the A. C. field switch in until the speed of the machine falls off, then open field switch.

The order to close the steam off before opening the main generator switch may be a little surprising, but I'll explain. An A. C. generator connected into the line with another machine will run in synchronism with that machine, electrically locked until the switch is opened. (This is not true of a D. C. machine, don't confuse the two.) Now if the switch is first opened and the turbine shut down last the voltage of the machine may, owing to heavy load on No. 2 and consequent high exciter voltage at exciter busses, be excessive, making it urgent to get the prime mover closed down quickly or else opening the A. C. field switch and breaking a strong field which is not desirable. Certainly the amount of resistance in the A. C. field may be sufficient to reduce the generator voltage to normal or less. If so, then it does not matter which is done first, a great deal must depend on the local conditions. The main thing is to avoid haste which is always contributary to false moves and to say the least undignified.

Now the feeders may be changed, putting in No. 2 and cutting out No. 1 without interruption. The same is true of the transformers. Closing the secondaries first and primaries last.

Changing the Voltage Regulators.

Close single pole D. C. magnet switches on No. 2 regulator, then single pole shunt field short circuiting switches. Now the two regulators are in parallel and the contacts of No. 2 should be vibrating, 1. 1., opening and closing. When No. 1 can be disconnected by opening the single pole switches in the reverse order to putting into service, for further instructions see instruction books.

The motor generators can now be changed over. Start the synchronous motor as already described. Voltage is now built up on the D. C. end, to about 1 or 2 volts above the busses, put in main switch (D. C.) and equalizer, take the load over on to No. 2 by adjusting equalizing rheo., then open No. 1 circuit breaker and equalizer and open motor A. C. switch, cut in A. C. and D. C. rheostats and when machine is about stopped open field switches.

Operating in Parallel on Peak Loads.

It may be necessary to operate both A. C. and D. C. machines in parallel on peak loads. The only problem presented is equal load division. D. C. machines will usually divide pretty well without much annoyance once the rheostats are adjusted. Of course they may require occasional adjustment. The A. C. machines will require careful adjustment of the A. C. field rheostats in order to operate at good power factor. The ammeter and K. W. Meter readings may or may not be an indication of the true load. A reference to the feeder ammeter should check up substantially with the sum of the two A. C. generator ammeter readings. When this is so and the power factor is good, there is no further adjustment required so long as the turbine governors are of the same

type and sensitiveness. In getting equal load distribution it will be necessary to adjust both the turbine governor and the A. C. field rheostats.

The synchronous motor excitation is so adjusted as to improve the power factor. A synchronous motor may be considered as a condenser of large capacity for condensing wattless current as well as load capacity.

Changing Over to Standby Central Station Service in Emergency.

The first thing to do is to synchronize the station with the standby line. This operation is exactly the same as synchronizing two machines, since that is what it amounts to, except that you bring the loaded machine into step with the central station, and adjust the station voltage to that of the line which may be slightly above or below the standby line value. You can do this when the difference is not greater than 15 per cent. up or down by adjusting the spring tension on the floating main contact of the regulator. When voltage is right and the point of synchronism reached close central station switch as described for generator.

You may now disconnect the regulator and cut exciter voltage down some before disconnecting main generator switch closing down the entire machine.

If standby D. C. is required the Station D. C. bussbar voltage must be brought to the same value as the standby when the standby switch may be closed and the station C. B. tripped. To change back again to station service reverse the operation. Note that the feeder circuits and transformers have not been interfered with. If the spare exciter is to be put in in an emergency it will be put on the exciter busses as already described for equalizing the exciters.

D. C. voltage regulators are practically the same as A. C., except there is no A. C. magnet. With compound wound D. C. generators voltage regulators are rarely necessary, as the total current generated passes through the series field and as the load is increased the field is correspondingly strengthened. A small winding called the Shunt Winding carries a small amount of current that can be increased or diminished for initial voltage adjustment. If the machine builds up too high a voltage where the load is increased it is said to be over compounding, and if it falls off it is said to be under compounding. This is partially remedied by putting on shunts to divert some of the current from the series field when the machine overcompounds and taking off shunts where undercompounding. If the regulation is poor it may be necessary to install voltage regulators. Under certain circumstances any variation whatever is objectionable—the limit of variation being one or two volts, or say 1 per cent. With a variable load the only solution is the installation of voltage regulators. In some cases a variation of 5 or 6 per cent. is not considered serious, and in such cases the regulation is always by hand.

Cutting In Generators.

Question.—Will you please tell me through your Power House columns how to put D. C. and A. C. generators on the line, also something about Switch Board operation? Our line voltage is 600 V. A. C. and 250 D. C.

Answer.—To answer this question properly will require too much space in the Question Box Department. It will be taken up elsewhere. A brief description of the operation however is as follows:

D. C. generators "starting up" with all switches open and no machines in line.

1st. Start the prime mover in the usual way and when up to speed.—

2nd. Note that the rheostat is turned in, that is all the shunt field resistance cut in.

3rd. Close field switch (single pole) some small installations have no field switch, the field being always closed.

4th. Build up voltage slowly by turning rheostat in the direction to raise voltage.

5th. Close circuit breaker.

6th. Close main switch.

7th. Close breaker on feeder circuit if there is one.

8th. Close feeder circuit switch.

9th. Adjust voltage with rheostat if voltage falls off with load.

Be sure to close C. B. before closing switch because if there is trouble on the line the circuit breaker will automatically clear the line the instant the switch is thrown in.

Taking D. C. Generators Out of Service.

1st. Open Feeder C. B.

2nd. Open Feeder Switch.

3rd. Cut in shunt field rheostat.

4th. Open C. B.

5th. Main Switch.

6th. Close down.

7th. Open field switch.

Note.—It is not really necessary to open field switch if care is taken to have the rheo. cut in, but should the rheo. be cut out there will be no resistance in the field and if the generator is started up with the field switch in the voltage may be high enough to break down the insulation.

Paralleling D. C. Generators.

Build up voltage on incoming generators as already described. If the generator on line has load build voltage on incoming machine up to about two volts higher than the line voltage. When this has been attended to close C. B. on incoming machine and close main switch. Lastly close equalizer switch, then equalize the load with equalizing rheostat or with generator shunt field rheostat, if there is no equalizing rheostat.

Taking D. C. Generator Out of Service Where There Are Two or More Generators on the Line.

1st. Reduce load on the generator to be disconnected. Do this carefully, letting the load be gradually taken over on the other machine, by slowly cutting in resistance in the outcoming machine. When load has been reduced open C. B. and main switch and close down prime mover.

In case of an emergency requiring quick shut down of one machine when there are two or more in service, simply open C. B. and main switch. The worst that can happen is a heavy swing of load on to the other generators, with consequent line disturbance. Always get the generator disconnected from the switch board before closing down the Prime mover.

The subject of cutting in and out A. C. generators is treated fully in an article appearing in this issue.

INSPECTING CLOSED BOXES BY X-RAYS

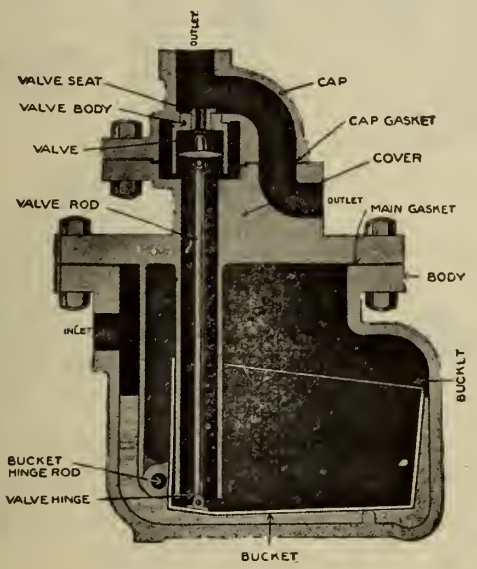
X-rays are a form of light which has the power of penetrating substances which are opaque to ordinary light. The more dense the substance the less it is penetrated, so that the rays falling on a composite body, such as a box with metal nails and hinges, throws a kind of shadow picture of the hidden parts on a photographic screen. This fact has been utilized in the examination of manufactured articles. Recently a British Government Department brought out a portable X-ray outfit for examining large numbers of boxes, without opening them, in order to see whether they contained all the essential parts. The apparatus is placed on wheels and is solidly built to stand rough use in the workshop. In place of a photographic plate a fluorescent screen is used so that the operator can actually see the shadow picture thrown by the contents of the boxes. By the use of this equipment an immense amount of time has been saved in the inspection of thousands of articles.

THE BRITISH INSTITUTE OF PHYSICS

The first scientific institutions in the world were formed in Great Britain; and to-day almost every branch of science is represented by a powerful body of British experts. The increasing specialization of scientific work has led during late years to a rapid multiplication of such bodies, the latest to be formed being the Institute of Physics recently inaugurated in London. One of the main objects of the Institute will be to afford increased assistance to research in pure science. Great Britain has always been pre-eminent in this branch of progress and it has achieved results of epoch-making importance at a wonderfully small outlay. With improved organization and increased resources it is expected that Britain's lead in the advancement of knowledge of the constitution of matter will be increased.

Strong Steam Traps

Save every Ounce of Steam



The Strong Steam Traps automatically remove the condensation from the systems or machines to which they are connected, and increase the efficiency of the machines themselves. This is made possible by the pumping or siphoning effect of the trap action upon the condensation in the steam apparatus.

The service rendered by Strong Steam Traps in respect to increased machine output at lesser cost, has resulted in the standardization of Strong Traps by a great many of the largest steam trap users in the world.

Strong Steam Traps are built extra heavy throughout and by changing the valves and seats, the same trap may be used under any pressure from zero to 200 lbs. In case of the discontinuance of a certain system, the traps may be removed and installed for other service.

The Strong Steam Traps are so constructed that only a few minutes are required to renew the only wearing parts, the valve and seat (no piping to disconnect).

Each Strong Steam Trap, upon completion and before being shipped, is carefully inspected and tested and leaves the factory in perfect working order and ready to go into service without any adjustments being required.

Our nearest Sales Office will send full information and prices on request.

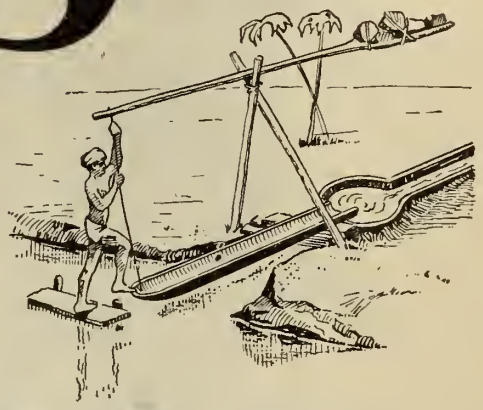
PUMPS

The Doon is simplicity itself. One end of trough dips into pool—stone weight comes down—trough tilts up—water flows into ditch!



In Oriental countries a tremendous amount of human labor is expended in comparatively small achievement. About the only recommendation of the Doon method of "pumping" is simplicity! This same elemental requirement—simplicity—is a vital principle of American-Marsh Pumps. They are built to render heavy and effective service.

American-Marsh Centrifugal Pumps are made in both single and double suctions, solid and split case patterns.

Write for American-Marsh bulletins.

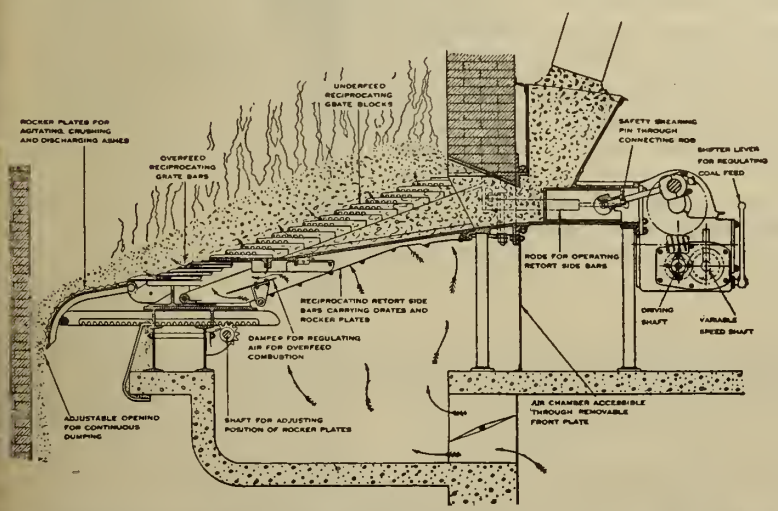
CLINKERS

Clinkers are a nuisance—no one denies that—but some grades of coal will clinker. The best way of handling them is the problem. Shall they be left undisturbed to grow into an immense fixed clinker or shall they be broken up as soon as they form and then gradually pushed down onto the dump and into the ash pit?



ROCKER PLATES FOR AGITATING, CRUSHING AND DISCHARGING ASHES
UNDERFEED RECIPROCATING GRATE BLOCKS
OVERFEED RECIPROCATING GRATE BARS
SAFETY SHEARING PIN THROUGH CONNECTING ROD
SHIFTER LEVER FOR REGULATING COAL FEED
RODS FOR OPERATING RETORT SIDE BARS
RECIPROCATING RETORT SIDE BARS CARRYING GRATES AND ROCKER PLATES
DRIVING SHAFT
VARIABLE SPEED SHAFT
DAMPER FOR REGULATING AIR FOR OVERFEED COMBUSTION
ADJUSTABLE OPENING FOR CONTINUOUS DUMPING
SHAFT FOR ADJUSTING POSITION OF ROCKER PLATES
AIR CHAMBER ACCESSIBLE THROUGH REMOVABLE FRONT PLATE

Years of study and experimentation in stoker design have evolved the Riley "moving grates" as the satisfactory solution to this problem.

Before the clinker gets a chance to spread, the reciprocating retort sides start slicing and pushing the clinker down to the rocker dump where it is continuously crushed and discharged.

And thereby is avoided costly burn-outs from the reverbatory action of flames under large fixed clinkers when left undisturbed.

Let the Machine do the work of breaking up and ejecting the clinkers instead of back-breaking labor on the part of the fireman.

There's more about the labor and fuel saving features of the Riley Underfeed Stoker in our Catalog HR-7. Ask for it.

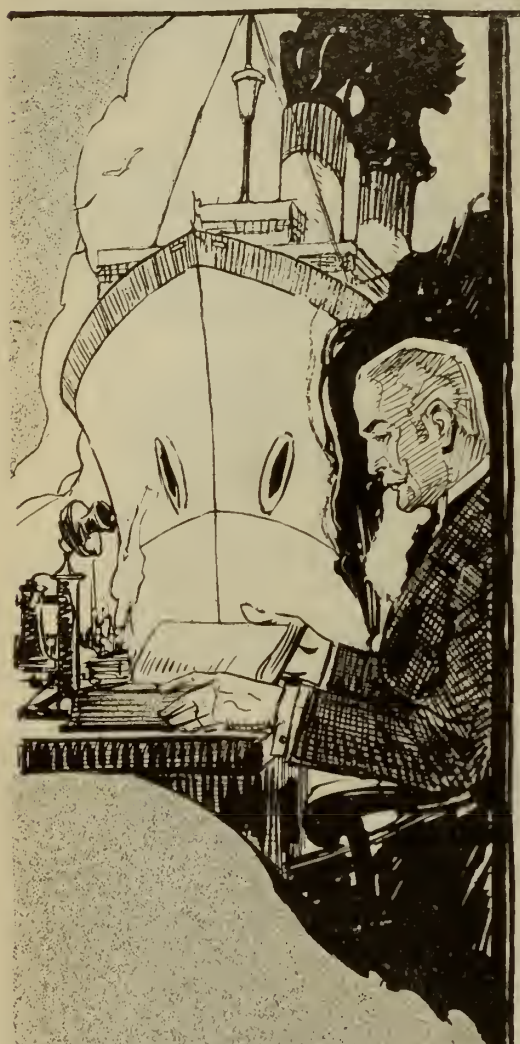
When a Wise Shipper Charters a Ship, He Looks Up Lloyds Register



He wants to know more than actual tonnage. The condition of the ship, her record, the reputation of her owner and skipper are all factors in his choice of a carrier.

His mental attitude is the same as that of the Scientific Space Selector who wants to know more about publications than a mere statement of "Net Paid Circulation."

The wise Space-Buyer keeps his copy of "Scientific Space Selection" handy and digs deep into the facts set forth in A. B. C. reports so that he can obtain authentic data on where the publication goes, and to whom it goes.

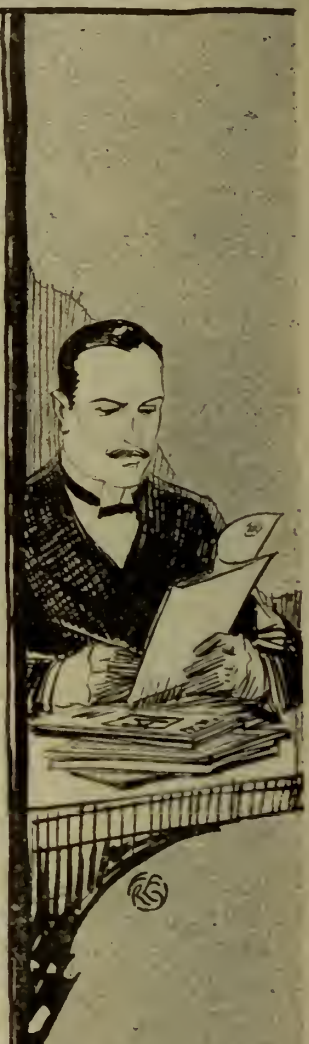
He also wants to know about the influence, stability and character of the publication in which he is going to buy white space.

All these facts can be obtained from A. B. C. reports. You'll find a carefully audited statement about circulation on the first page and, if you read pages two, three and four, you'll be able to visualize the character of the publication and to answer the question, "Will this medium help to sell my goods?"

The capacity for taking infinite pains becomes, every year, more applicable to Space Buying. Exaggerated claims, misleading figures, general statements are looked upon with critical eyes. Deductive reasoning dominates space selection, as it does every other business proposition.

That is why A. B. C. reports represent the back bone of space buying. They are correct, informative, and clearly set forth

— but to reap the full benefit of A. B. C. reports they must be studied for more than the mere statement of "Net Paid Circulation."



Be sure to get your copy of "Scientific Space Selection," the new A. B. C. book. A guide to every advertiser, space-buyer and publisher who is interested in the sale or purchase of white space. *Price, two dollars and a half.*

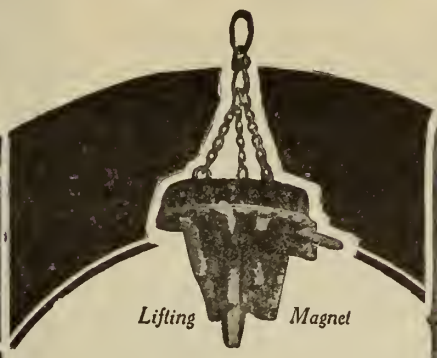
CUTLER-HAMMER

Automatic Starter



Lifting Magnet

Compensator

Magnet and Control Devices

¶ Cutler-Hammer Lifting Magnets and Magnetic Separators have proved of exceptional value in the mining field, in steel mills and in many other industries for lifting and separating metals. The Magnetic Clutch and electrically operated Brake, used primarily in steel and rubber mills and for crane control repectively, are widely applicable to many industries where the gradual engagement or adequate braking of a load is desirable.

¶ In electric controlling devices of all kinds Cutler-Hammer is the recognized standard of dependability, whether for fine speed adjustment of a machine, extremely close voltage regulation, the wonderful light dimming and colour effects in a modern theatre, or the automatic control of heavy loads or other special operations.

¶ Details and recommendations of suitable Cutler-Hammer apparatus for your control problems are available at our branches.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS
An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.
E. H. KELLOGG & CO.,
New York, U.S.A.

SITUATIONS WANTED—MALE

STATIONARY ENGINEER (2ND CLASS)—would appreciate steady position in country; references A1. Apply, mentioning Power House, to Box 218, Globe.

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House.

STATIONERY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers. Corliss and all classes of stationary engines, compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St., Toronto.

POSITION WANTED BY AN EXPERIENCED refrigerator engineer, also competent in ice making and electricity. Address, D. M. J., Power House, Toronto. (p1h)204

MONCRIEFF'S

Moncrieff's "Unific" is not a cheap glass. But because it outlnsts mnny ordinary glasses the "Unific" is economical. British Made.

"UNIFIC" WATER GAUGE

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

GLASSES

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

Canadian Representative: W. J. WALL, 134-136 Bleury St., MONTREAL, CANADA

How to Test Advertising

THE man who doubts the power of advertising belongs in the same class with the man who refuses to believe that the world is round simply because he can't get off somewhere at a distance and see its roundness for himself.

The merchant who fears to attempt advertising because he figures it as an "expense" is blind to his own interests. I personally know several men who, because they once tried advertising to the extent of a cheaply printed hand-bill and didn't find it necessary next morning to call on the police to keep the crowds of eager buyers from swamping their store, loudly and solemnly aver that "advertising doesn't pay."

Advertising *does* pay.

The most successful merchants are the merchants who believe most thoroughly in advertising and who practice their belief.

But advertising, in order to pay, has got to be *intelligent* advertising.

The day of hashed-over superlatives — "best goods," "lowest prices," "best stock in town," "greatest bargains ever heard of," and so on—has passed.

People have learned to distinguish the *truthful* advertiser from the blatant behind-the-times storekeeper who believes that, so long as *he* claims to have the best goods on earth, or under the earth, or within wireless distance of the earth, people will break their necks trying to get to his counters in the forefront of the crowd.

Put some *brains* into your advertising.

Don't let the office boy write your announcements in between his other duties.

Don't doubt the business-getting and business-building power of intelligent and informative publicity — and you will find that advertising *does* pay.

—Jerome P. Fleishman.

It Brings Returns

in money saved, in coal saved, in time saved, to invest in

PLIBRICO JOINTLESS FURNACE LINING

A furnace lining full of joints means loss of money through loss of heat and rapid deterioration. There are NO joints in a PLIBRICO lining, therefore no loss of heat—no coal waste—and deterioration cannot start.

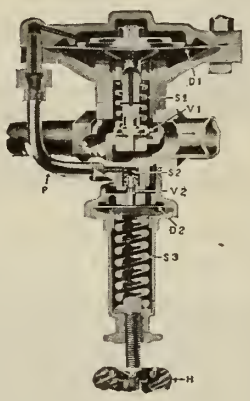
A PLIBRICO lining is quickly and easily installed, a saving in time. Therefore PLIBRICO is a big-paying investment.

Shipped in steel containers of distinctive appearance as shown at the right.

Warehouse stocks in Montreal, Toronto, Winnipeg, Vancouver and Calgary ready for immediate delivery.

Ask for book L-12 on Furnace Building.

FISHER
TRADE MARK REGISTERED



LOW PRESSURE CAN'T BUILD UP

If you manufacture a product requiring curing, drying, bleaching, dyeing, vulcanizing, evaporating, or any other process dependent upon a uniform temperature or pressure you will certainly be interested in

FISHER PRESSURE REGULATOR
Series 90

It will accurately and consistently deliver any desired reduced pressure to apparatus.

It will also shut off absolutely tight when low pressure is interrupted. Pressure cannot build up on the low pressure side.
Like all other Fisher specialties this valve is distinguished by excellence of material and workmanship.

Actual service in thousands of plants throughout Canada has proven Fisher Power Plant Specialties to be long-lasting and accurate in the most trying and delicate operations.

Ask your dealer or jobber for full information about the Fisher line. Or write for "POWER PLANT SPECIALTIES." It is full of interesting information. We will gladly send you a copy. Write today.

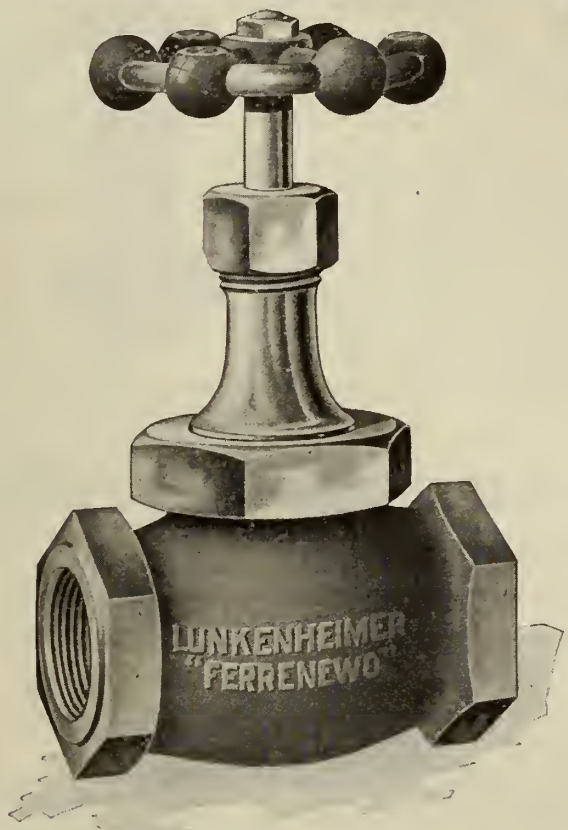
LUNKENHEIMER
"Ferrenewo" Valves



"FERRENEWO" Valves are *economy* valves, proved so by their record of years in service. Low initial cost, wear resisting materials and the ease of renewal of all the parts should necessity require, makes them highly desirable for piping equipment where the pressure does not exceed 150 pounds.

LUNKENHEIMER "Valve-iron" from which "FERRENEWO" Valve bodies are made is an especially alloyed and processed Ferrous Composition. The renewable *seatring* and *disc* are made of LUNKENHEIMER "Valve-nickel," while the bonnet, stem and bonnet ring are made of bronze compositions formulated especially for the duty each part performs.

The "FERRENEWO" material combination and unique design, coupled with the LUNKENHEIMER method of manufacture insures successful results under the wide range of operating conditions for which "FERRENEWO" Valves are adapted.

LUNKENHEIMER Distributors situated in every commercial center carry "FERRENEWO" Valves in stock for immediate delivery.

To standardize on "FERRENEWO" Valves is
to *economize* in valve cost and maintenance.

JONES "A-C" STOKERS

It's The Cost of Stoker *Service* That Counts

PLANTS that have installed Jones "A-C" Stokers have found that the most expensive stoker is the hand stoker. Why? Because the cost of hand firing per ton of coal fired is excessive and beyond reason. Yet there is no first cost to hand firing.

Bear this in mind in selecting a mechanical stoker to overcome the exorbitant expense of hand firing. Forget first cost and choose the stoker that costs least per ton of coal fired.

The records of Jones equipped plants prove that there are a number of sound reasons why you buy your stoker service cheaper when you choose the Jones "A-C."

It will save MORE coal—by burning a wide range of poor coals with high efficiency. The Jones under-feed principle insures that.

It will give greater boiler capacity—by carrying heavy overloads continuously.

It will save in maintenance costs, for it is the simplest, most rugged high-duty stoker.

The new "A-C" catalog will convince you that stoker service costs least per year when you operate the Jones "A-C." Where shall we mail your copy?

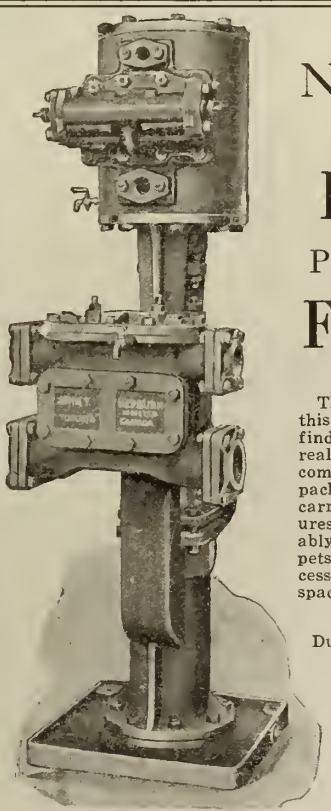
Low Cost Coal Storage with "LABRIDE" Equipment

If you are unloading coal by hand, the "LABRIDE" Equipment will save you from 70 to 95 per cent. of your coal handling cost. This equipment consists of a moving bridge traveling lengthwise of the storage space and a bucket trolley traveling crosswise on the bridge,—thus every square foot of storage space is covered with a minimum of movements and time. The "LABRIDE" Equipment is the fastest, most efficient and economical method known in coal handling today. Capacity varies from 60 to 90 tons per hour.

Write or wire for information.

Lakeside Bridge & Steel Co.

159 VillardAvenue, North Milwaukee, Wis.



NO EXCUSES
With the
HEPBURN
Patent Vertical Ram
FEED PUMP

There are no excuses attached to this Hepburn Patent Pump. You'll find that out if you give it some real work to do. It is a sturdy, compactly constructed, outside packed type for Feeding Boilers carrying the highest steam pressures. The construction is remarkably simple and eliminates all tappets and levers. Every part is accessible, and it takes little floor space in the Power House.

Duplex Pumps, Vertical Engines, Compressors, Hand and Electric Overhead Cranes for Power House Service are also products of the Hepburn plant.

Mueller Tools for Gas and Water Works

When you find the name *MUELLER* on any tool, it means that no better tool has yet been made for that particular need.

MUELLER Pipe End Reamers (A 3201), Pipe Jointers (A 3166), Gas Main Bags (A 3162), Seamless Steel Ladles (A 3163), Steel Melting Pots (A 3171), Lead Melting Furnaces (A 3150), are but a few of the ***MUELLER*** Standard Tools—all of which are illustrated and described in ***MUELLER*** Catalog A, which will be sent on request to any interested Company.

Mail orders given immediate attention. It is advisable to place orders early.

PACKING ECONOMY

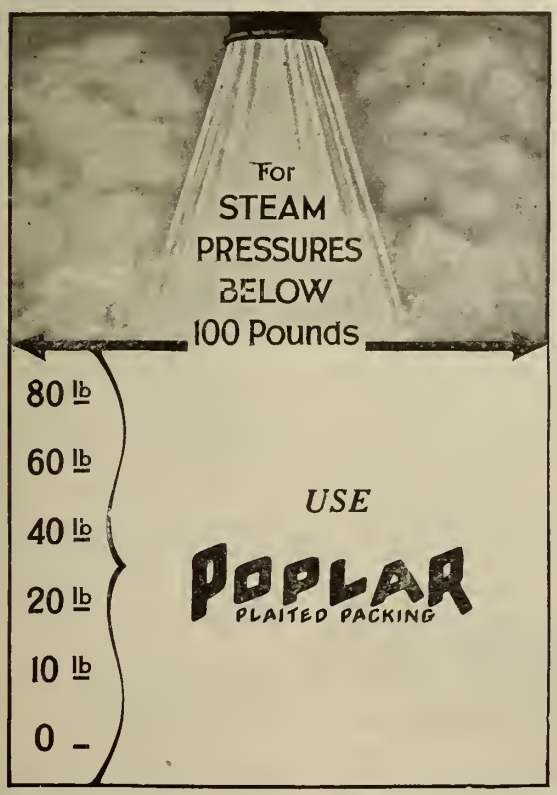
In these days a good engineer carefully studies his operating costs, and as far as packing is concerned he can keep the expense down by using a packing adapted to each particular service.

There is no sense in using an expensive packing under moderate conditions when a less expensive one will answer.

After considerable experimenting we are able to offer you at a very moderate price our "POPLAR" Packing for hydraulic and low steam pressures.

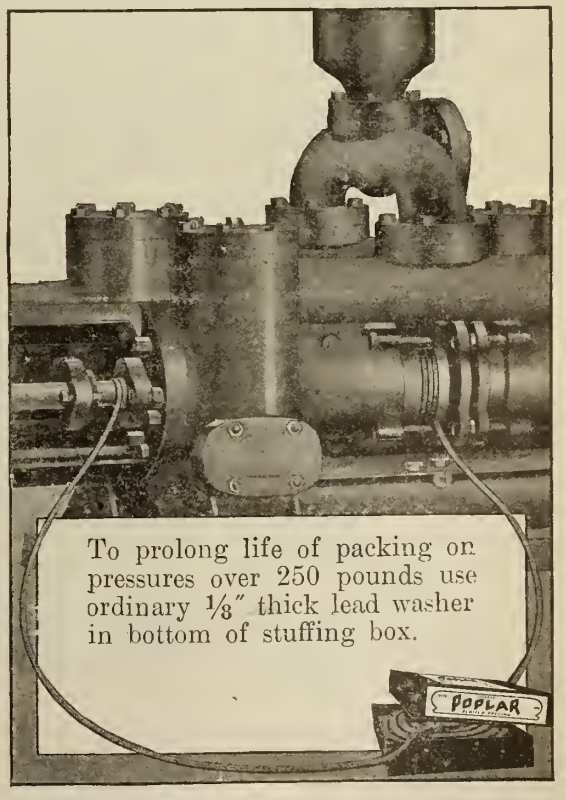
It has high tensile strength, with our unusually thorough method of single strand lubrication of graphite grease, and for the services for which it is designed can be depended upon to give satisfactory service.

"POPLAR" PLAITED PACKING IS PRACTICALLY FRICTIONLESS



WHY NOT GIVE "POPLAR" PACKING A TRIAL?

GREENE, TWEED & Co.
Sole Manufacturers
109 Duane St.
New York



To prolong life of packing on pressures over 250 pounds use ordinary 1/8" thick lead washer in bottom of stuffing box.
POPLAR

MacKinnon Steel Co., Ltd., Sherbrooke.

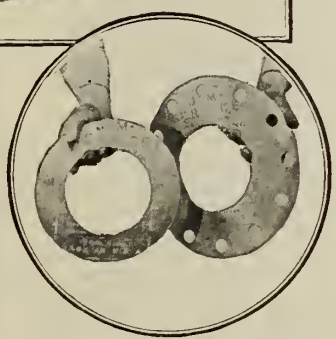
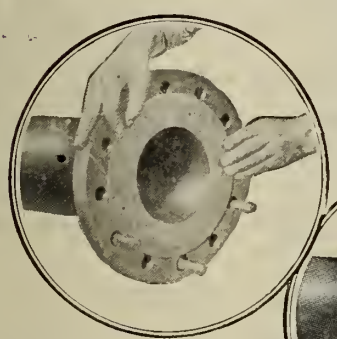
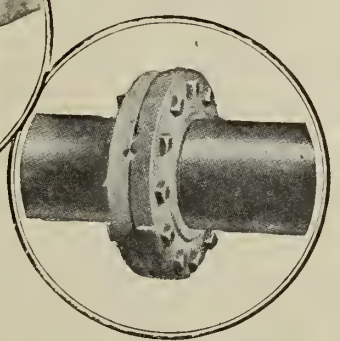
A Ring Gasket cut from Johns-Manville Service Sheet Packing makes a long-lasting tight joint.



Note the difference in size between the Full Gasket and the Ring Gasket. With the same pull on the bolts there would be nearly twice as much pressure per square inch on the Ring Gasket as there would be on a Full Gasket.



A Ring Gasket is easy and quick to cut and apply. There are no bolt holes to fuss with. Cut your Ring Gaskets from Johns-Manville Service Sheet Packing.



If the flanges happen to be irregular or burred, a Ring Gasket is the solution because it doesn't reach out to the damaged edges of the flanges.

Better joints— with smaller gaskets

THE way you cut a gasket often determines the reason for blowouts or tight joints, packing waste or packing economy. You know there are two distinct types of gasket that may be cut from the same sheet for packing pipe and other flanges—these are the full cut type and the ring type both shown in the illustration.

We advocate and recommend the use of the ring type gasket because it makes a tighter, better, more economical joint than the full cut gasket.

Here's why:

1st—The ring gasket allows a greater and more uniform pressure to be brought against the gasket—more pounds per square inch of packing area than is possible with a full gasket.

2nd—Irregularities on the flange or burrs on the outside edges are less likely to prevent a perfect fit with the ring gasket than with the full gasket which reaches to the very outside edge of the flange.

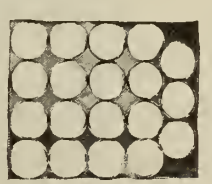
3rd—The ring gasket is more easily made and applied because there are no holes to match up with the bolts or studs which have to pass through a full gasket.

4th—Much less material is required for making ring gaskets.

If you have been guided largely by habit in the use of full gaskets, we suggest that you try ring gaskets and cut them from Johns-Manville Service Sheet No. 60.

CANADIAN JOHNS-MANVILLE CO. LIMITED

Toronto Montreal Winnipeg Vancouver
Hamilton Ottawa Windsor



You can cut about 50% more Ring Gaskets than Full Gaskets will do a better job—particularly if they're cut from Johns-Manville Service Sheet Packing

BOWSER OIL FILTRATION SYSTEMS

ESTABLISHED 1885

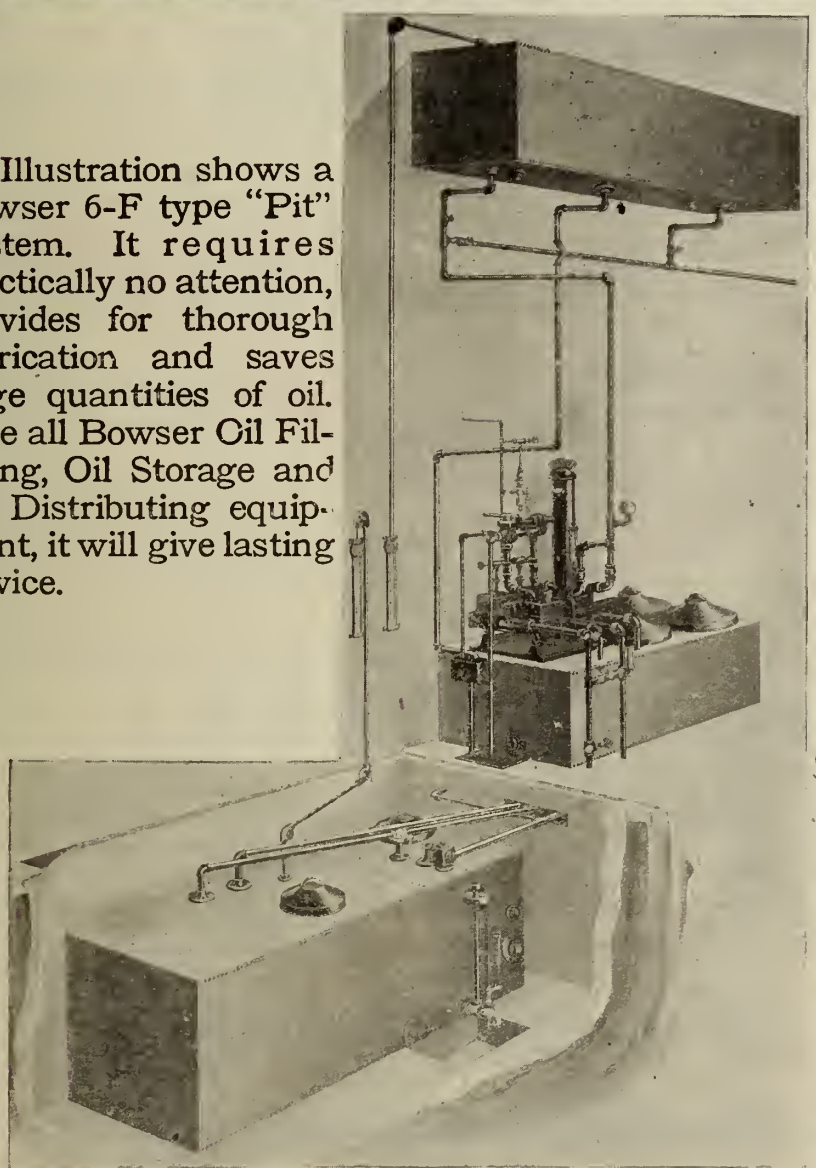

Illustration shows a Bowser 6-F type "Pit" System. It requires practically no attention, provides for thorough lubrication and saves large quantities of oil. Like all Bowser Oil Filtering, Oil Storage and Oil Distributing equipment, it will give lasting service.

provide the most efficient method of lubrication for rolling mill, gas or steam engines, for any moving part requiring lubrication.

The Bowser System provides plentiful lubrication at all times. It reduces the consumption of oil enormously by filtering and using the oil over and over. It increases production or power output by reducing friction and preventing breakdowns from worn out or burned bearings.

Let our engineers tell you of representative installations, suggesting how you can save by filtering your oil. Their co-operation and their experience is at your disposal.

A Float That Doesn't Collapse

The American Ideal Trap has a heavy Hercules float made of seamless, non-corroding copper. It will resist pressures up to 600 lbs. to the square inch and is guaranteed for the life of the trap.

But in spite of its heavier construction, this float responds instantly to the slightest rise in the level of the condensate because of its powerful valve leverage.

AMERICAN IDEAL STEAM TRAP

keeps lines thoroughly drained at all times.

If you select your American Ideal Steam Trap on the basis of its guaranteed capacity in accordance with our tables, you will be surprised to find how completely your trap troubles will be overcome.

Size for size, American Ideal Steam Traps handle much more condensation than ordinary traps, and on this basis and length of service, the American Ideal is the cheapest trap on the market.

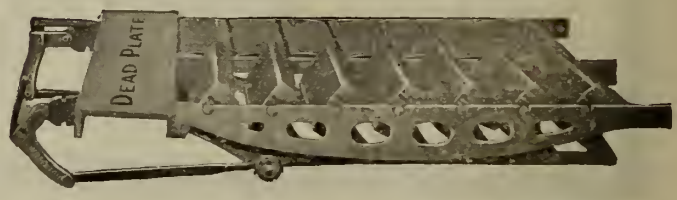
What Do You Do With Your 10th Dollar?



Every time Brown spends Ten Dollars for coal, Jones, his competitor spends only nine. Figured out in terms of a year's supply Jones makes quite a saving. Why? Simply this. Jones uses Nonpareil Grates and saves 10% of his bills. You also can save that 10th Dollar by installing these economy grates.

AGENTS WANTED

Good opportunity for engineers or practical men.

NONPAREIL GRATES

Shaking and Dumping

MORRISON'S STEAM GOODS

The J.M.T. Reducing Valve

"Every installation is a demonstration of merit"

Since the introduction of this J.M.T. Valve there has been no "problem" of pressure reduction of air and steam. A sudden change in the low pressure demand, or variations in flow and pressure on the high pressure side, have no effect on the constant low pressure maintenance.

The Morrison catalogues give full particulars of this and the other Morrison Steam Goods. Have you a copy?

Aeroplane View of the Berliner Gramophone Company's Plant, St. Henry, Montreal.

"His Master's Voice" People use Jenkins Valves

Fig. 106
Jenkins Brass Globe Valve
Standard Pattern

Successful manufacturers like the Berliner Gramophone Company realize the importance of dependable equipment at every point and, naturally, "Jenkins" is the choice wherever valves are used.

Many years ago Jenkins Valves were installed in the original Berliner plant and functioned so satisfactorily that the Company insisted upon similar valve equipment in the big new factory addition recently completed.

Jenkins Valves are sold by supply houses everywhere. Know the genuine by the Jenkins name within a Diamond Mark Cast on the body.

(Trade Mark Registered)

WATER SOFTENING SYSTEMS *and* RAPID PRESSURE FILTERS

BOOTH LIME-SODA WATER SOFTENERS

REFINITE Systems are acknowledged the standard of the world. REFINITE mineral is a natural water softener—not a chemical product. These systems are in wide use in the United States and other countries and in British Colonies throughout the world. Complete engineering service is maintained for efficient and dependable operation after installation.

Let us demonstrate the economic value of REFINITE soft water in reducing fuel costs, increasing production and insuring higher grade work in manufacturing, laundering and power stations and plants. Full particulars, catalogs, etc., sent upon request.

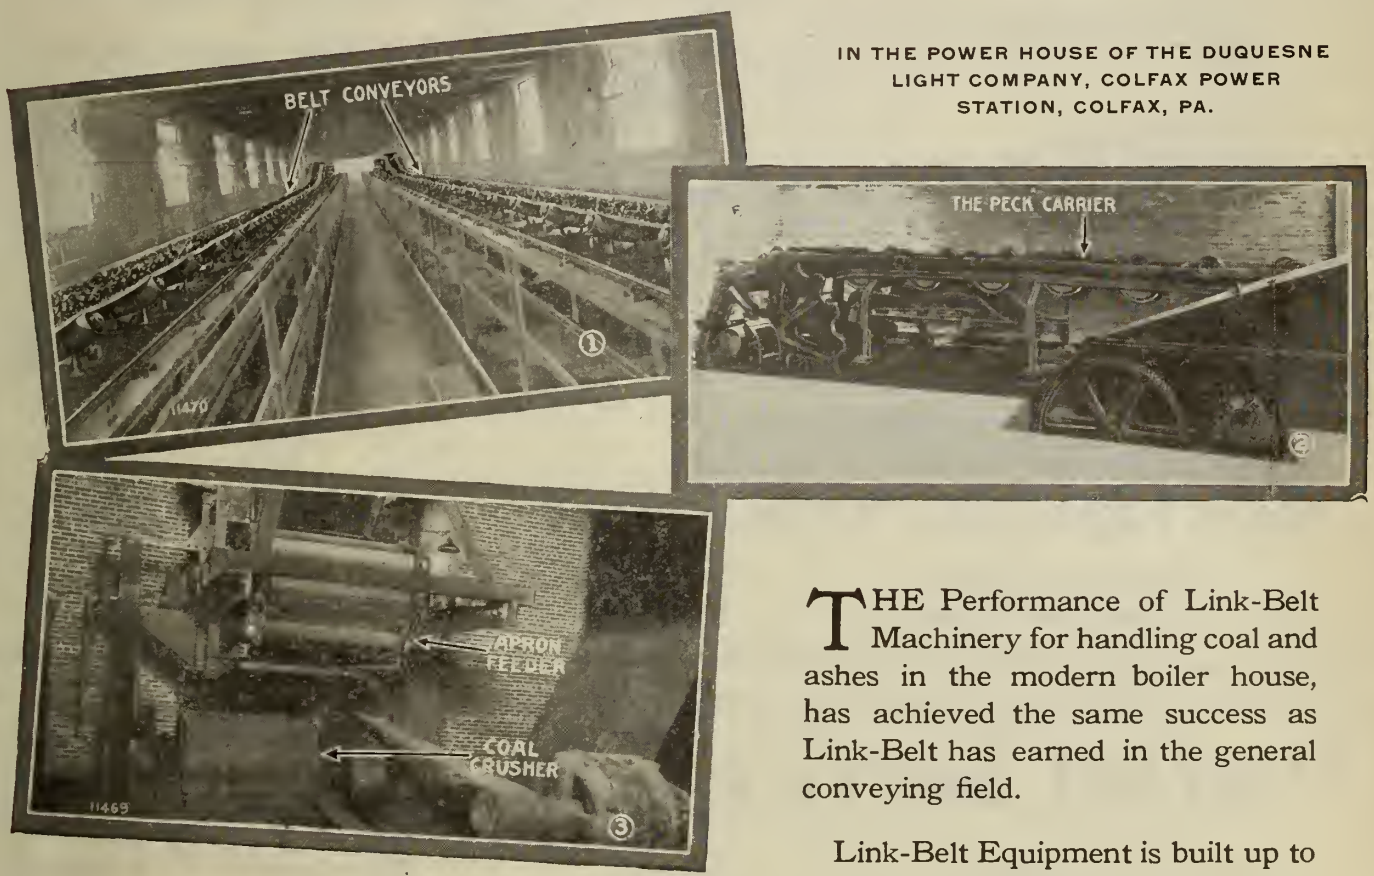
LINK-BELT

COAL AND ASHES CONVEYORS



IN THE POWER HOUSE OF THE DUQUESNE LIGHT COMPANY, COLFAX POWER STATION, COLFAX, PA.

1. Two 480 ft. Centers Belt Conveyors.
2. The Peck Overlapping Pivoted Bucket Carrier.
3. Coal Crusher and Feeder.

THE Performance of Link-Belt Machinery for handling coal and ashes in the modern boiler house, has achieved the same success as Link-Belt has earned in the general conveying field.

Link-Belt Equipment is built up to a high standard—not down to a low price. It is rugged, durable, reliable. We guarantee its successful performance. In the long run it costs less than low-first-cost machinery.

Let us show you why.

Perfect Service Gasket Material

Guaranteed to make a Tight Joint wherever a Permanent Gasket is required.

Place DURABLA in the next joints you make and be insured against a costly shutdown.

DURABLA

TRADE MARK REGISTERED

Strength; Goodness; Quality - these features distinguish Durabla Gaskets.

DURABLA Sheets can be rolled and unrolled; it never dries out or opens up.

DURABLE Compressed Asbestos Fibre Gasket Material is a guaranteed product that can be used as a standard for all Gasket work. DURABLA Gaskets make tight joints on Steam, Water, Oil, Ammonia and Acids at all temperatures and pressures.

DURABLA is not affected by vibration or condensation. It will not burn out, blow out or pulp at the points.

Let us send you a trial sample. Made in stock sizes 36 in. wide x 144 in. long, and 48 in. wide x 144 in. long, in thicknesses of 1-64, 1-32, 1-16, 3-32, 1-8.

Orders Filled Promptly.

Correct Lubrication Increases Profits

MACHINERY that is perfectly lubricated with Imperial Lubricants, *wears less* and *lasts longer*. Gives maximum service, too, in every working operation. That's why superintendents and plant engineers all over the Dominion depend upon Imperial Oil Limited for their lubricating oils.

Imperial Lubricants are scientifically tested, and graded. Each grade is of unvarying high quality. From the list on the left you can select the *right* lubricant for every type of machine in your plant. Ample supplies are always conveniently available.

Correct Lubrication of all your plant units is the sure way to avoid rapid depreciation, costly shutdowns and repairs. Correct Lubrication reduces even the cost of lubricating your plant.

The regular use of Imperial Lubricants guarantees power-saving economy, increased efficiency and more profitable plant operation.

If in doubt about your present lubricating practice, Imperial Lubrication Engineers will be glad to advise you. Write to 56 Church St., Toronto.

QUALITY YORK SERVICE

York Semi-Enclosed Refrigerating Machines

The Raw Water Ice Plant is rapidly taking the lead, and its development demands an Ammonia Compressor that is most economical in Power Consumption.

Where electric current is available at a reasonable cost, our Semi-Enclosed Machine, with direct motor mounting, makes a neat, clean and highly economical plant—no belts, no engine or steam lines.

The machine occupies a comparatively small floor space.

All the power developed by the motor is delivered to the crank-shaft of the machine.

These machines are built in sizes from 30 tons refrigerating capacity upwards.

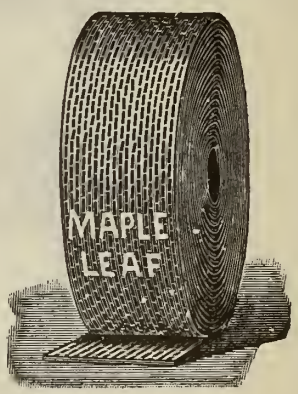
Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO., Ltd., Hamilton, Canada - Quebec Branch: 51 Duluth Bldg., Montreal

The Safe and Certain Boiler Cleanser

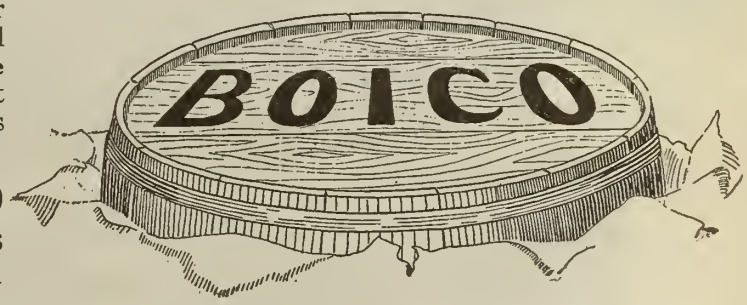
PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

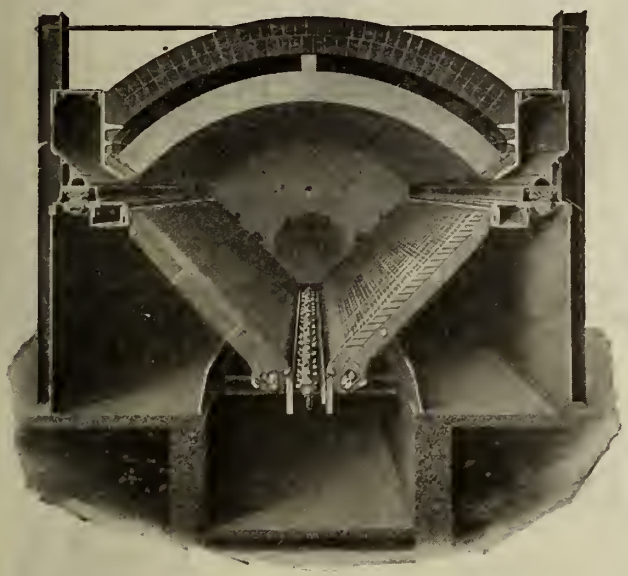
Reducing the Cost of Steam Making



Back in 1907 the New York Air Brake Co. became interested in the possibilities of savings to be made by using

MURPHY AUTOMATIC FURNACES

in place of hand-firing methods. A test made on a 150 h.p. boiler, hand-fired, showed a cost of 20.39 cents per 100 lbs. water evaporated. A Murphy was then put in under this same boiler, reducing the cost to 14.49 cents per 100 lbs. of water evaporated.

This *demonstrated saving,* together with smokeless operation and low maintenance, has led to *three repeat orders* received from this company.

At that time coal cost $2.95 a ton at their plant—to-day that won't cover the freight per ton to most plants.

Think how much more tne Murphy can save at today's coal prices!

Find out what a Murphy can do for you in your plant. Send for Catalog HM-7.

For information on RILEY UNDERFEED STOKERS for large boilers, see advertisement in last issue or send for RILEY STOKER Catalogue HR-7.

Low Cost Coal Storage with "LABRIDE" Equipment

If you are unloading coal by hand, the "LABRIDE" Equipment will save you from 70 to 95 per cent. of your coal handling cost. This equipment consists of a moving bridge traveling lengthwise of the storage space and a bucket trolley traveling crosswise on the bridge,—thus every square foot of storage space is covered with a minimum of movements and time. The "LABRIDE" Equipment is the fastest, most efficient and economical method known in coal handling today. Capacity varies from 60 to 90 tons per hour.

LUNKENHEIMER

"Vigilant" Safety Water Column

A *safety appliance* necessary for protection against the dangers incident to high and low water levels in steam boilers.

THE "VIGILANT" SAFETY WATER COLUMN will automatically sound an alarm and notify the attendant whenever the water level approaches either danger limit. It thereby safeguards life and protects the boiler from serious disaster which may be caused by the low level allowing the fire to play on the crown sheets and tubes when unprotected, or extreme high level which causes priming of the boiler and consequent damage to the power unit and the connecting pipes and valves.

The action of the "VIGILANT" operating mechanism is simple but positive. The single float actuates the double acting valve through the medium of stops set for high and low level limits. When the water approaches either danger limit the valve is opened, permitting steam to pass and blow the signal whistle.

A sediment chamber is provided at the bottom to trap scale or dirt which may enter the Column; Gauge Cock connections are tapped on both sides to permit right or left hand assembly; the top is removable for inspection of working parts, and all parts are renewable.

The "VIGILANT" Safety Water Column is recommended for working steam pressures up to 250 pounds; is made in a variety of sizes to suit all makes of boilers, and from the extensive line of LUNKENHEIMER Water Gauges and Gauge Cocks available a combination can be selected to suit every individual installation.

Specify LUNKENHEIMER "VIGILANT" Safety Water Columns and insist on getting what you specify.

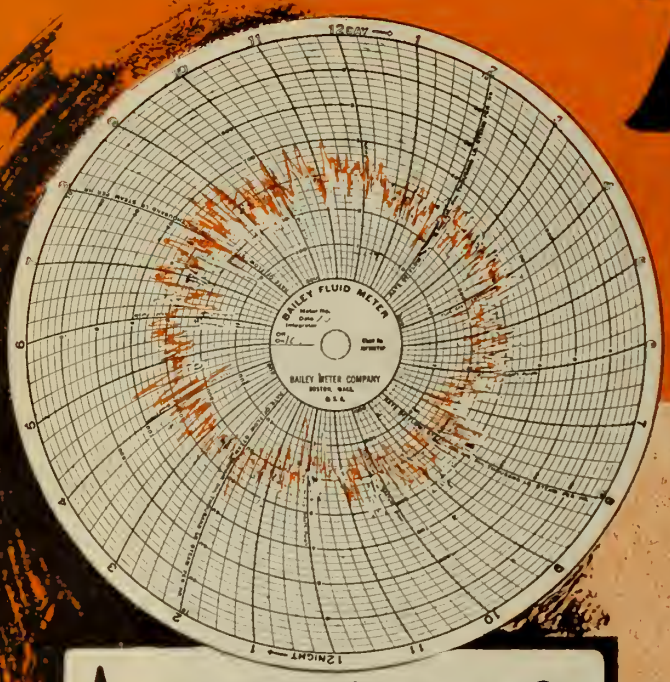
The Chart Continuous



Average Load for 12 Hours 267% of Rating

THE charts above—made during two successive days—are merely representative of two weeks of continuous day and night overloads, met without a single hitch by Jones "A-C" Stokers installed under 320 H.P., B. & W. Boilers in a big paper mill*. A plant capable of making these charts is ready for any load demand.

Eight boilers are equipped with Jones "A-C" Stokers, which replaced natural draft mechanical stokers so that greater ratings and efficiency could be secured.

Note the chart above, showing an average of 27,000 lbs. of steam per hour—equivalent to 267% of rating. The period between 8 and 12 o'clock on the chart at the right shows an average reading of 30,000 lbs. of steam per hour.—equivalent to 297% rating.

"The grade of coal used made no difference in rating," said the Combustion Engineer, "for we produced with Coal of 14,000 B. T. U. down to 11,400 B. T. U."—the grade of coal burned in many Canadian plants.

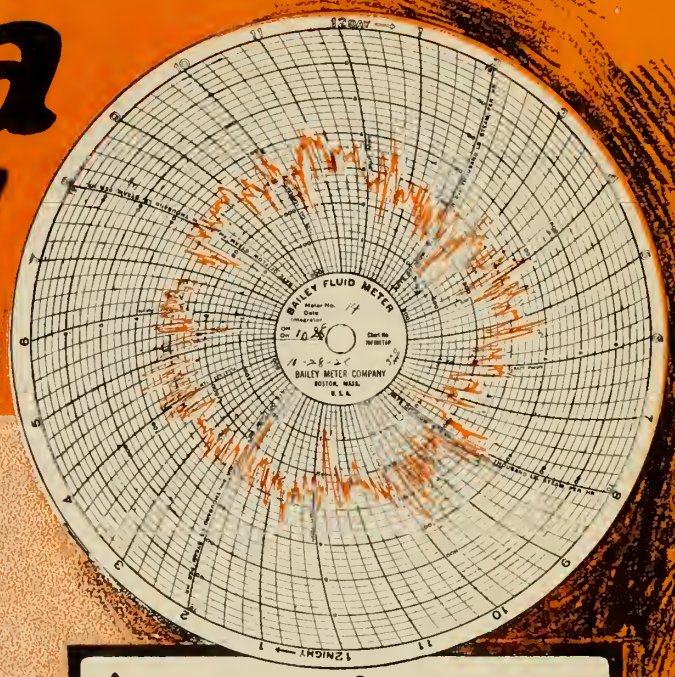
This excellent performance, coming after two weeks of hard driving, emphasizes an advantage that is shared by all Jones installations

**Name furnished on request.*

Pays for Itself— Then Pays Dividends

Jones

Story of a Overload



Average Load for 4 Hours 297% of Rating

--The Jones "A C" is not only capable of meeting heaviest overloads, but-- what is more important--it will stand the gaff of continuous overloads.

This is because the Jones "A-C" is simpler and more rugged in construction than any other multiple retort stoker of the same general class.

There are no crankshafts, gears, gear shifts, chain drives, or shearing pins to cause trouble; no complicated dumping mechanism; instead, the simple, hand operated balanced dump plate that has proved its superiority.

The one and only moving part within the furnace is buried deep in the green coal. Shut-downs for repairs are practically eliminated.

Why results like those recorded by the charts can be duplicated in any Canadian plant day in and day out, is fully explained in the new "A-C" catalog. You have your copy?

The Hamilton Plant of the Canadian Cottons Ltd.

The Steam Plant, Which Has Been Installed to Supply Steam For Process Work and Heating, is of the Most Modern Design, and Embodies Interesting Features.

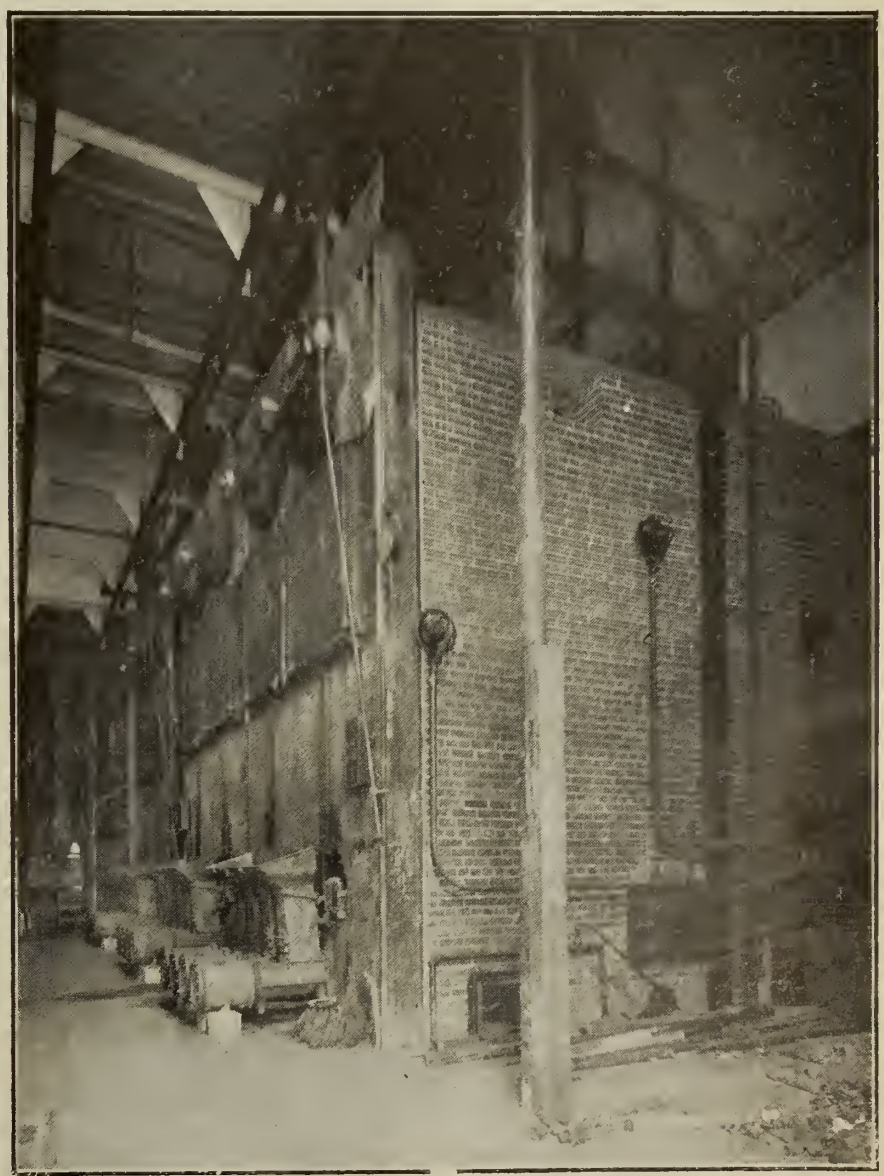
BY T. H. FENNER

THE Canadian People are continually demanding more cotton and textile goods. In order to supply their demand a very large milling industry has grown up in the Dominion. New mills are being built, and the existing mills are adding to their premises and doubling up the number of spindles. One of the latest additions to an existing mill is the new building of the Canadian Cottons on MacNab Street in Hamilton, and the increase in the manufacturing capacity has necessitated the installation of a very modern steam generating equipment. Through the courtesy of the management, we were enabled to make an inspection of this plant, and secure some good photographs for the benefit of POWER HOUSE readers. The plant is almost entirely devoted to the generation of steam for process purposes, practically all of the power being obtained from outside sources, the only exception being in the dyeing room, which is driven by an engine. This on acccount of the necessity of absolutely uninterrupted operation, which is a sine qua non of successful dyeing, and an interruption to the service on the outside of the mill would entail considerable damage and loss.

The General Arrangement

The general arrangement of the plant can be seen from the various photographs reproduced here. The building itself is square, and stands in a court yard formed by the buildings of the old factory, and from the outside does not look particularly like a power plant, the principal point which makes one recognize it being the ash shute projecting from one end. Any doubts about the purpose of the building are quickly dispelled when the doorway is entered. Standing at the doorway in the west corner of the power house, from which one of our photographs were taken, the boilers are in front to the right. The firing platform in front of the boilers is of ample width, and the travelling hopper which weighs and delivers the coal from the overhead bunker is seen in the passage. The boiler room is divided lengthways by a concrete partition, behind which are situated the feed water heater, the fan for the forced draught to the boilers with its two engines, the feed pumps, the hot water circulating pumps, and the water softening outfit. There are two galleries above this pump room, the first one containing the heater for the factory water, and the hot water storage tank, while the gallery above is given up to the soft water storage tank, and a regenerating tank for the water softening plant. This top gallery is on a level with the boiler tops, and communicates with them by means of an iron grating.

At the east end of the boiler room are situated the coal handling and ash



VIEW OF FIRING PLATFORM, SHOWING STOKERS AND SOOT BLOWERS.

handling apparatus, and there is a broad basement under the boiler room floor for handling the ashes into the conveyor. Good solid iron ladders and gratings are provided for getting up to the galleries, and the whole plant gives one an impression of compactness and convenience without any crowding.

The Boiler Installation

The amount of steam that is required for the operation of a mill of this kind can be judged by the boiler installation. There are at present three Goldie and McCulloch boilers of the B & W waters tube type, each one rated at normal capacity for 430 horse power. Besides this, provision has been made for the addition of a fourth boiler. The present capacity is thus practically 1300 horse-power at normal rating, and the boilers can be forced to 225 per cent of rating, or 125 per cent over the normal. This would give a capacity of practically 3,000 h. p. on the present installation when run to their highest overload, and with the fourth boiler 4,000 horse power per hour could be achieved. In terms of water evaporated per hour this means that with steam at 130 lbs. per square inch and feed at 180 degrees there would be at normal rating 41,262 pounds of water evaporated per hour while at the 225 per cent rating the evaporation would be 92,839.5 pounds.

The boilers are noticeable for being set very high above the grates in the approved modern fashion, and one cannot help but contrast the arrangement as it stands with the old fashioned idea of setting the boiler right on top of the grates. It is one of the contrasts that calls one's attention to the progress in engineering which one is too apt to take as a matter of course.

The boilers are fitted with the Jones A. C. underfeed stoker, and each boiler has four retorts under it. These stokers are guaranteed to deliver 225 per cent rating on the boilers for a period not exceeding four hours, and a steady load of 150 per cent rating. They work under forced draft, and automatic regulation. The efficiencies guaranteed are 76 per cent at normal rating, 75 per cent at 150 per cent rating and 73 per cent at 225 per cent rating.

The rate of working the stoker is controlled by the automatic regulators which can be seen in front of the partition. These regulators are the Cole Automatic valve, and are in turn controlled from the fan engine. The fan engine is controlled by a sensitive control valve in the steam line, which automatically increases the speed of the engine if the steam pressure drops. This again increases the revolutions of the automatic valve controlling the number of strokes per minute made by the stoker, and steam is brought up rapidly. The fan engine slows down with the increase in steam pressure, and the stoker in turn slows down. The regulation is very close. Each stoker retort has its own valve, and these can be adjusted without interfering with any of the others. Thus in a four retort stoker, such as is fitted in this installation, it might be necessary to adjust the valves on the two outside stokers to give more strokes per minute than the two inside ones. This adjustment would be independent, the general control still being obtained from the fan engine. The Cole automatic valves are driven by a belt the driving pulley being keyed to the fan engine shaft.

VIEW OF BOILER TOPS AND FRONT, FROM GALLERY.

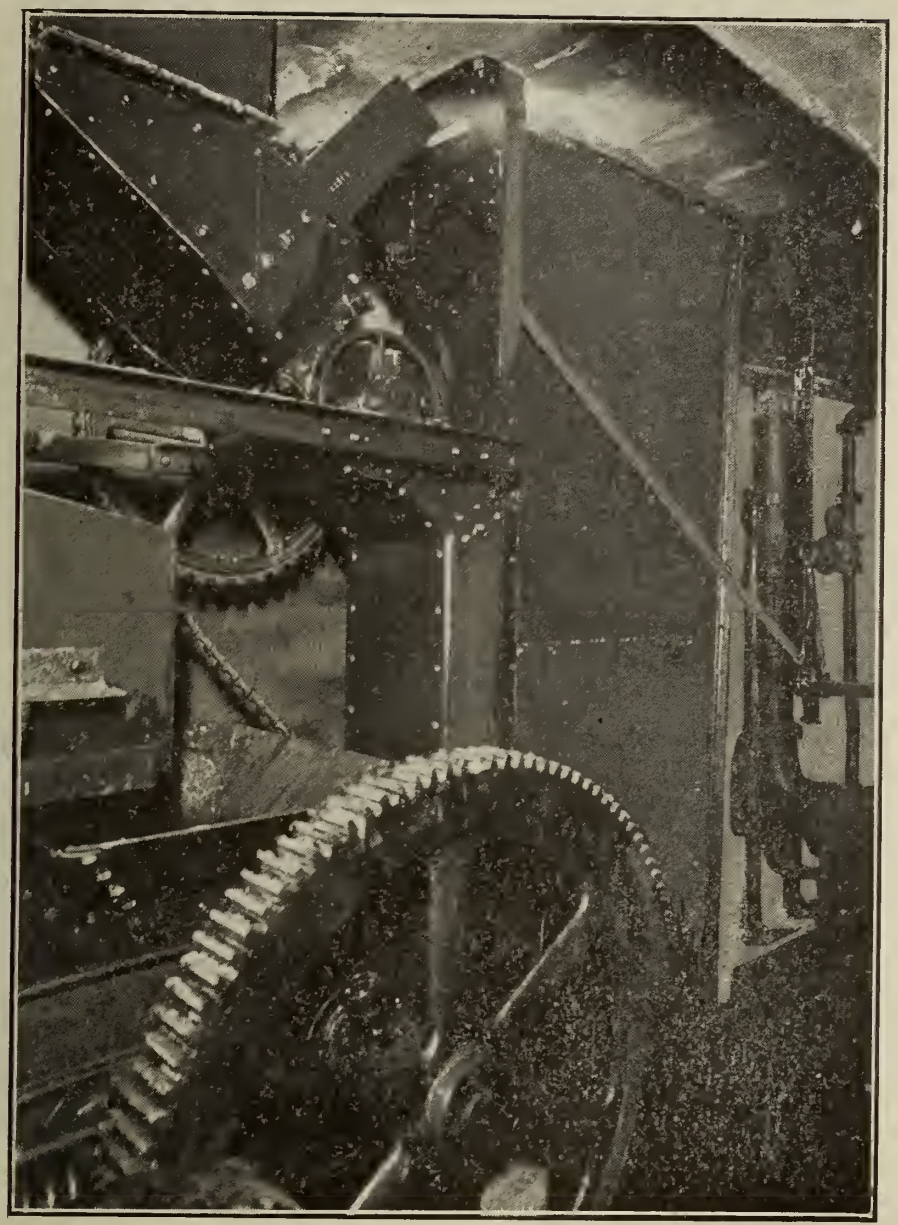
On the front of each boiler setting there is a three-in-one draft gauge made by the Precision Instrument Company. These gauges are easily read from any position on the firing platform, and tell the operator at a glance the static pressure at the fan discharge, over the fire, and in the last pass of the boiler. These readings convey at once an indication of the state of the fire, and also of the baffling, and condition of the tubes as far as the soot deposits are concerned. If the baffling is not in good conditon there will naturally be very little drop between the furnace and the back pass, while on the other hand, dirty tubes by causing higher resistance would indicate a greater drop than normal between these two points. In order that the tube may be kept as clean as possible, each boiler is fitted with a set of Diamond soot blowers.

Coal Handling Plant

It will be seen that thus far the firing of the boilers is taken care of with practically no human handling. This principle has been carried out throughout the plant as far as practicable, and a complete coal and ash handling system is included in the installation, supplied by the Canadian Link Belt Co.

The coal coming into the plant is delivered on the outside of the power house to a hopper, which delivers it onto a shaking platform. The opening of the hopper is covered with a grating having a 12 inch mesh. The shaking platform runs the coal into the opening of a 23 inch by 24 inch two roll coal crusher, and from this it drops into the boot of a vertical conveyor. It is elevated by this conveyor up to the roof of the building, and then delivered into the working bunker, until this bunker is filled, when the coal is spilled over into the reserve bunker. From the working bunker the coal descends by gravity into the hopper of the traveller which weighs it before delivering it to the stoker hopper. This travelling weighing hopper has a capacity of half a ton, and is moved along the boiler fronts by hand. The coal is weighed automatically and a ticket is punched on the scale within easy reach of the operator on the boiler room floor. In order to reclaim the coal from the storage bunker when required, a chute is led from the bottom to the boot of the vertical conveyor, and in this way it is delivered again up to the daily needs bunker. There is also a by-pass provided around the coal crusher, so that coal can be delivered direct to the elevator without going through the coal crusher if such practice should be necessary. The coal crushing and conveying machinery is electrically driven, and the control is situated in the boiler room, in a small room at the side of the boilers. An ingenious electrical locking arrangement is provided on the control, by which it is impossible to start the crusher without at the same time starting the elevating conveyor. On the other hand the conveyor can be started without the crusher. This eliminates all danger of getting the machinery jammed up through the coal being delivered to the crusher with no means of taking it away, and this safe guard was introduced on the initiative of Mr. Piers the supervising engineer of erection.

When the coal has fulfilled its purpose in the furnace, and given up everything but the incombustible material it contains, the ashes are dumped by the stokers into the sloping ashpit, which leads to the tunnel under the boilers. These ashpits are furnished with large doors, opening outwards, and the ashes are pulled or descend by gravity onto



THE COAL CRUSHER.

the floor of the tunnel. Directly opposite each set of ashpit doors, there is an opening in the floor communicating with the 8 in. American Steam Conveyor ash conveyor. and they are drawn into this, and blown up to the ash bunker, which extends nearly the whole height of the building. This bunker which is of large capacity, is furnished with a chute at the lower end, and this chute projects into the space over the coal receiving hopper. Carts can be backed under here, deliver coal, and if necessary take away the ashes on the return load. All the driver has to do, is to open the gate on the end of the chute and his cart is filled with ashes automatically.

The photograph shows a view of the ashpit tunnel, the round pipes overhead being the air ducts from the fan to the furnaces. The up-going pipe of the ash conveyor can be made out in the far right hand corner.

The Steam Pipe Arrangement.

When one looks at the photograph of the boiler tops the impression of ordered neatness is very striking. The writer was much impressed by the appearance when he reached the top of the ladder leading to the third gallery on which is contained the storage tank for soft water. This gallery is on a level with the boiler tops, and one gets a very good view from there. The photograph which perforce had to be taken from one end does not quite do justice to the general effect which can be obtained when one stands in the middle The writer has had so many painful experiences of boiler tops that were dirty, dark, dusty and uncomfortable that he is able to appreciate a pleasing layout when he stumbles across one

The tops of the boilers are insulated with a covering of Armstrong cork brick, which makes a very nice finish, and looks as though it will stand being walked on without disintegrating The safety valves, of which there are two on each drum, or four to each complete boiler, have a waste pipe on each drum leading through the roof, while a drip is placed in the elbow of each waste pipe to keep the pipe drained The main steam pipe is taken from the centre of the header joining the two drums, and is furnished with a Crane non-return valve The large bends used for expansion purposes can be well seen in the illustration, and form practically a semicircle The three pipes from the boilers are connected on to a main header which can be also plainly seen, and from this header are taken the pipes to the mill, and to the auxiliaries in the boiler room. At the centre of the header, or between boilers 2 and 3 can be seen two large valves which serve the purpose of isolating one half of the header from the other, so that steam can be supplied from either side quite independently. The main steam to the mill is taken off the header right between these two valves, while the steam supply to the feed pumps, water softener, fan, engine, etc., is taken from branches which are in duplicate on each side of the dividing valves. The same idea is used on the feed header which runs along the front of the boilers, the discharges from the two feed pumps being connected in at either end.

The Pump and Fan Room.

Leaving the top of the boilers reluctantly, and passing the middle gallery with its machinery for the time being, we reach the ground floor and pass behind the dividing partition into the fan and pump room. The water softening plant is at the far west end of the room, the fan occupying with its engines the centre, while the feed pumps and heater, together with the circulating water pumps are at the east end.

There are two centrifugal pumps, one driven by a Terry steam turbine and the other electrically driven, to supply hot water forced circulation for heating the new buildings A storage tank on the gallery above, is connected with a Griscom Russel heater, and this heater supplies the heat to keep the water in the circulating system to the required temperature. All the returns from the steam pipes in the mill are delivered to a Cochrane heater, the exhaust from the fan engines, pumps, etc., also going to this heater. The rated capacity of this heater is 1,300 horse power, and it has a heating capacity of 53,000 lbs. and a metering capacity of 60,000 lbs. water per hour. It is equipped with two V notch meters each of which have a capacity of 30,000 lbs. per hour, and the water going to the feed pumps passes over these notches. The exhaust inlet is twelve inches and the outlet is ten inches in diameter.

The water is delivered from the heater to the boilers by two Weir feed pumps, manufactured in Canada by Peacock Bros., Montreal, the size of these pumps being 7 x 9½ x 15. Either pump is capable of supplying the boilers but the pumps are in duplicate in line with the general policy adopted in the construction. Each pump is controlled by a Chaplin-Fulton vigilant regulator.

The Sturtevant fan which supplies the air for the Jones stokers has a capacity of 34,000 cubic feet per minute at a static pressure of four inches water. There is an engine at each side of the fan, and these are attached to the fan

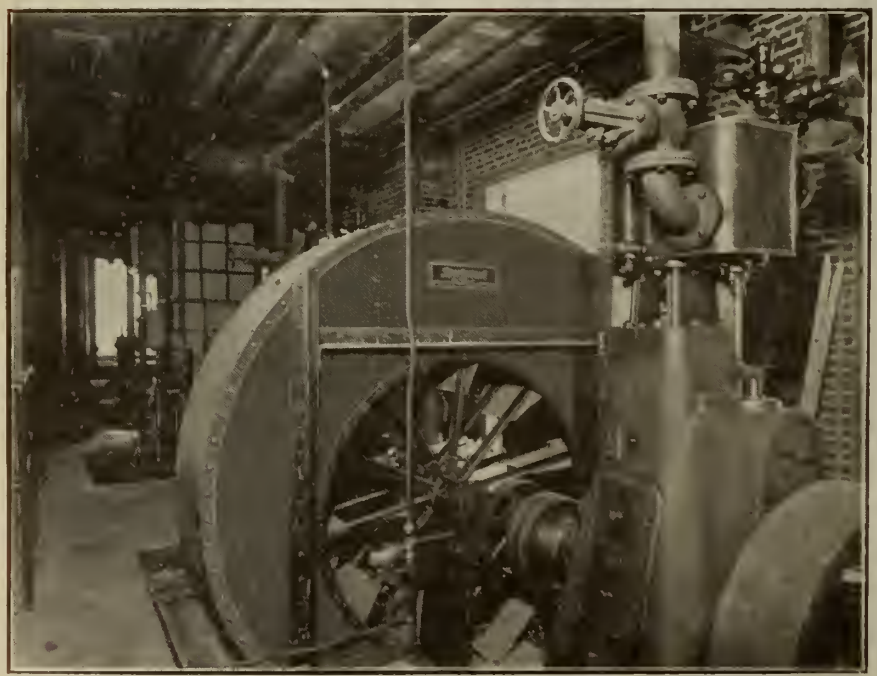
shaft by means of flexible couplings. Our illustration shows one of these engines and the fan, while the feed pump can be seen in front of the heater. The pumps are of course sunk in a pit below the heater in order to get away from any trouble due to vaporisation of the water in the suction. The Ruggles Krausmann Regulator is behind the fan and cannot be seen in the illustration. There are pulleys on each fan shaft for driving the Coles regulators previously referred to. The air is delivered from the fan through the ducts shown in the illustration of the tunnel. The fan is not in duplicate, but there is little necessity for such a course, the providing of duplicate engines being all that is necessary. The likelihood of any mechanical breakdown occurring to the fan is remote. The size of fan and engine can be well appreciated from the illustration.

THE ASH TUNNEL SHOWING FORCED DRAFT DUCTS.

The Water Softening Outfit.

The factory as before stated pumps its water from the Hamilton Bay, and this water as our readers are no doubt aware, is of a very turbid nature, so that it is absolutely necessary that it should be filtered for process work. In addition to this it is necessary to get as soft a water as possible, and the plant installed gives a water of zero hardness. The equipment is manufactured by the Permutit Co. of New York and is the same as that installed in the Canadian Cottons plant at Cornwall, Ont. Its capacity is 4,000 gallons per hour, or 40,000 gallons for a ten hour day, and the water delivered is absolutely free from all scale making minerals. It is claimed that with this system of water softening the boiler cleaning is entirely done away with, as there is absolutely nothing in the water to be precipitated when it reaches the boiler.

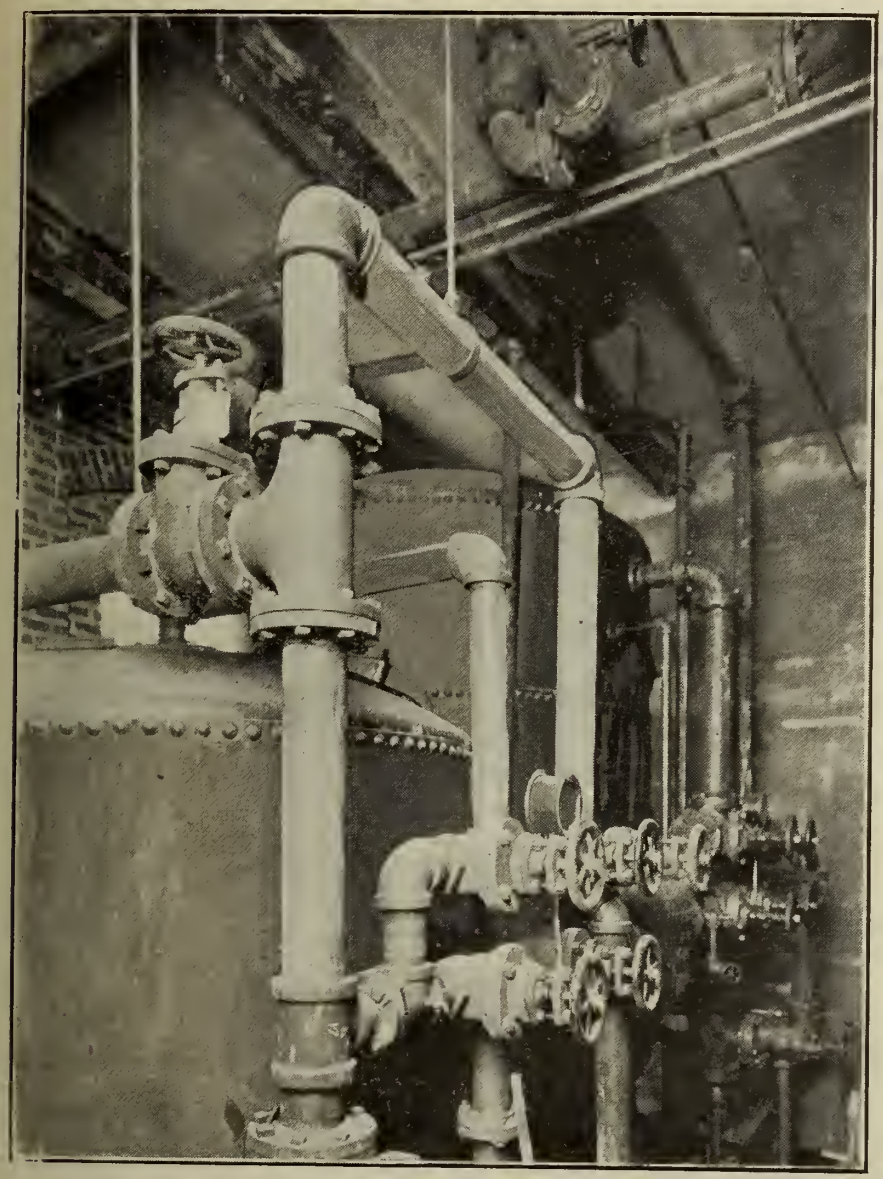
The water coming from the bay passes through the 72 inch diameter vertical clarifyng filter and from there goes through the 90 inch diameter vertical clarifying filter and from there goes through both these vessels. These vessels can be seen plainly in the illustration. After passing through the softener the water goes to the storage tank on the gallery which is shown in another illustration. The capacity of this tank is sufficient to meet the peak load requirements, and also to keep the plant going while the regenerating process is going on.



THE FORCED DRAFT FAN

The process is based upon the properties of a chemical substance known as "Zeolite," which are a form of crystals, and possess the property of being able to exchange their chemical base for that of bodies to which they are brought in close contact. This property is known to be possessed by fertile soils, and it is believed that the presence in the soils of these crystals is the cause of this power. The main constituent is silica.

The use of this property commercially was first made possible by Dr. Robert Gans, and his process was acquired by the Permutit Company. Dr. Gans produced a synthetic crystal which is absolutely insoluble in water, and possesses the property of giving up sodium to

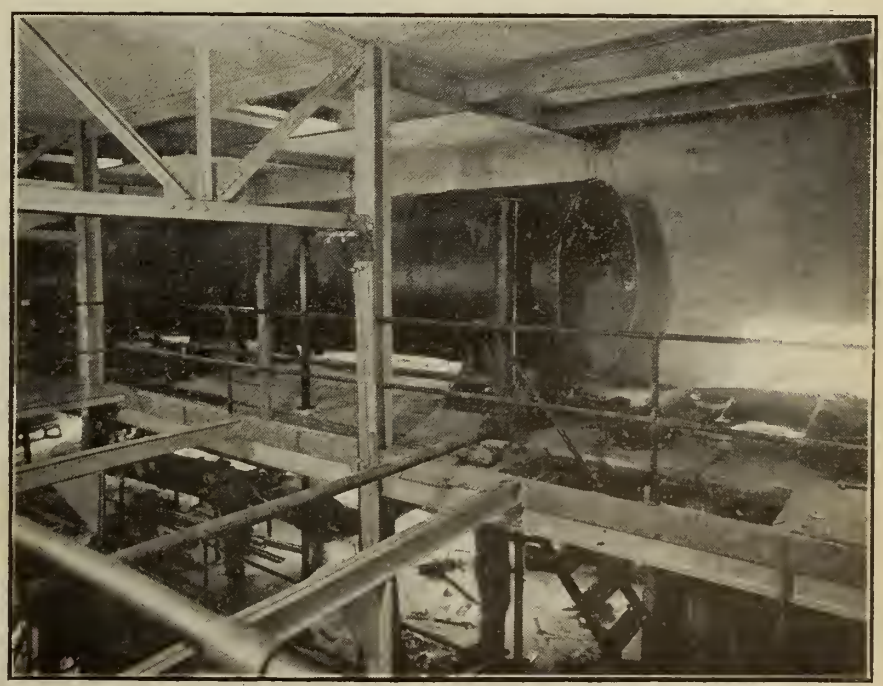


THE WATER SOFTENER

the water in exact proportion to the quantity of mineral contained in it, and absorbing this mineral. The process is thus one of exchange, the sodium in the "Permutit" being given up for the calcium and magnesium in the water. Another property of the "Permutit" is that after being in use for some time it can be restored to its original efficiency by simply soaking it in brine. In this operation the reverse process takes place, the calcium and magnesium being thrown off and the sodium from the brine is taken up. This leaves the "Permutit" ready to take up the excess over again. This reverse exchange is called "Regeneration."

The "Permutit" Zeolite is insoluble. For this reason a great excess of the re-agent can be placed in the filter to drive the reaction to completion, producing a water of zero hardness without the possibility of the treated water showing the presence of the excess. Only an exchange of hardness for sodium is possible and only as much sodium is given up by the "Permutit" as is required by this exchange. If the water is harder it gives up more sodium; if it is softer it gives up less; in this way the softened water is automatically kept free from the excess of chemicals and causticity. When the "Permutit" filter has produced its designed quantity of zero water, as may be seen by a water meter attached, the regeneration follows. The "Permutit" is back-washed for a few minutes, the brine is admitted with a syphon arrangement into the bottom of the softener, passing slowly up through the "Permutit" bed for eight to nine hours. The salt is re-claimed to the salt tank after regeneration. By the time this salt water is forced out of the "Permutit" filter, by the pressure of the incoming raw water, back into the salt tank, the filter is ready for its next operating run. The cost of treatment, therefore, is that of salt for regeneration. Common salt is used, which costs in bulk about three-quarters of a cent per pound, and in this case 7¾ pounds of salt is required for every one thousand imperial gallons of water softened. The "Permutit" Zeolite depreciates in quantity from 2 to 5% per year. In other words, a tank holding 200 pounds with a depreciation of 5% would have to have but four pounds of new material added yearly.

Have Bought Equipment.—Edmonton city council has decided to purchase a 5,000 k.w. Canadian General Electric Company's turbine, with Wheeler condensor, for use at the power plant. The price of the turbine and condensor will be $171,000, but the total amount involved, including installation, new drafts, ash handling plant, and other improvements and accessories, will come out at about $250,000. An order for the unit has been given and delivery guaranteed not later than three months. According to the statements of the firm's representative, the unit should be ready by October.



SHOWING SOFT WATER STORAGE TANK.

A Course of Instruction for the Graded Certificate

This Article, Which Will be the Last of the Series, Gives a Few More Examples of Indicator Cards, Dealing Especially With Those of Compound Engines.

BY T. H. FENNER

IN taking cards from a double acting engine it is always the practice to take them each end, one immediately following the other, and if used to the job, a man can usually indicate both ends within the space of three revolutions. This gives an opportunity to get a card from each end while conditions are pretty much the same in an engine with a variable load. Of course where a load is absolutely steady as in the case of a ship's engines in fine weather, there is no need for much haste. In the case of a high speed automatic engine direct connected to a generator, there may be considerable fluctuation of the load within the space of a few revolutions.

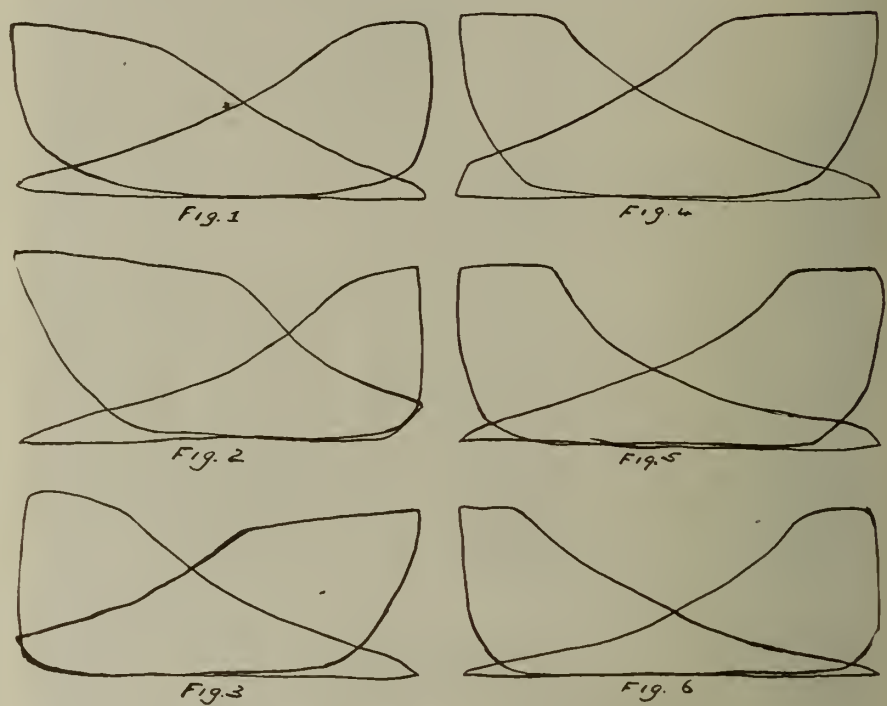
The two diagrams being on the same card give excellent opportunity to study the comparative dimensions of each and also to get the power developed at each end of the cylinder, the mean of which is the power of the engine. The object is to have the valves so set that the mean effective pressure at each end of the cylinder, or rather on each stroke, shall be the same, the power developed being slightly different on account of the diameter of the piston rod decreasing the effective diameter of the piston on the crank end of the cylinder. Sometimes allowance is made for this in working out the power, but more often it is neglected, the error on the total power not being more than about 2½ %. In large power engine this is negligible unless very accurate results are required.

The first example shows the effect on the card of the angularity of the connecting rod, when this is not counteracted by the setting or design of the valve. The cut off on the crank end is earlier than on the head end, and this induces a lower mean effective presure than that on the head end, which, coupled with the area of the rod, and the extra compression, makes a very much unbalanced engine.

Figure 2 shows the card that would be taken if the slide valve were too near the crank, due to wear or faulty setting, and Figure 3 the effect when the valve is too near the head.

The remedy for figure 1 is to increase the lead on the front end, until the cut off is equalised, or if anything a bit later than the head end, while in the case of Fig. 2 or 3 the valve must be adjusted by moving it on the spindle, or altering the length of spindle where that is provided for.

Figure 4 is an example of a Corliss engine with single eccentric, where the knock off cams on the steam spindle have not been properly adjusted, thus making the cut off unequal at either end. It must be remembered that in engines with a drop cut off gear, the adjustments have to be made on the governor arms, provided the eccentric is set correctly. Of course, for the opening to steam the correction must be made by means of the steam rods, the reach rod, or the eccentric itself.



SOME MORE EXAMPLES OF CARDS.—SEE TEXT.

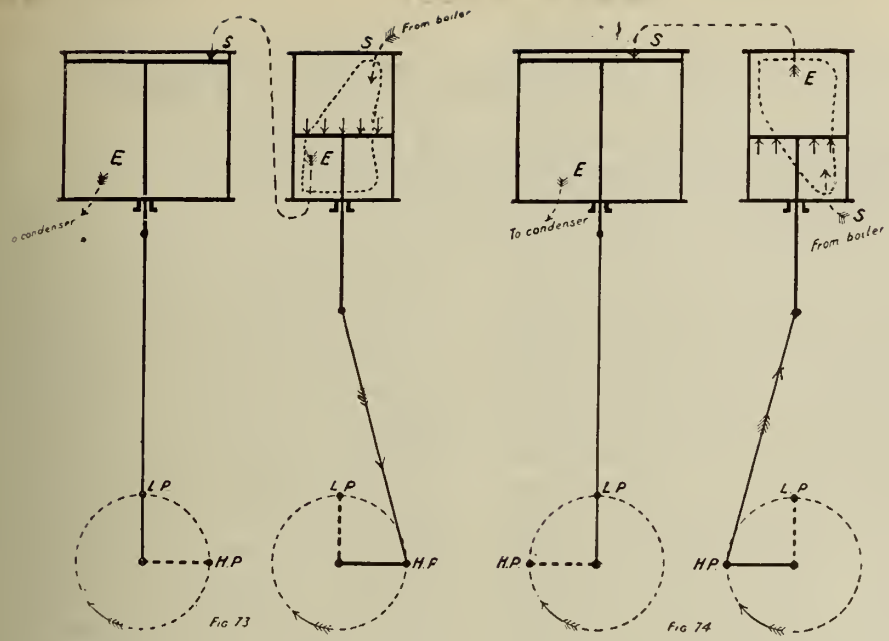
Fig. 5 shows cards from a Corliss engine with everything correct, cut offs equal, leads the same, and compression about the same.

Let us consider now a case where these conditions do not exist due to faulty setting. On the head end the lead is late, cut off is early, while exhaust opens at the right time, and compression also occurs at the right moment. On the crank end the lead is early, cut off is early while the exhaust opening and closing are correct. Let us see what defects this would point out. At first glance, lead early and cut off early would incline us to say that the eccentric was too far ahead, but the fact that the exhaust functions are correct at both ends, and this is a single eccentric engine, shows that the eccentric must be correct. It also shows that the length of the reach-rod must be correct, otherwise the exhaust valves could not be right at each end. This narrows the search down to the steam arms and the governor rods

Taking the valve openings first. On the head end the lead is late, or in other words, the valve is late in opening to steam. This means that the steam arm has got to travel a longer distance than it should in order to pick up the latch hook which turns the valve swindle. Then we must bring the steam arm closer to the latch hook, or in other words shorten the length of the arm. On the other end the lead is early and the cut off is early. If the lead is not excessively early it will be better to leave this as it is, and consider the cut off. Now we have at the head end an early cut off, and also at the crank end the same thing. This means that at both ends the latch hook is knocked off too soon by the knock off cams, and in order to remedy this we must lengthen the reach rod between the two cams, which moves the cam on the head end farther back, and the front end farther forward, thus making the cut off later at each end and adjust the main governor rod to suit the altered length of the reach rods. These adjustments having been made the cards should be about right.

Supposing instead that the exhaust on the head and crank end had been wrong while the steam end was right. This would mean simply that the reach rods from the wrist plates to the exhaust valve arms would have to be adjusted. If the exhaust opens too late and closes too early the remedy is applied by decreasing the amount of lap which the valve has over the edge of the port, and this is done by shortening the rod.

In the case of a Corliss engine with two eccentrics, if the exhaust valves both show too early opening and closing, or too late opening and closing, then the eccentric must be adjusted. If the



SHOWING EFFECT OF SEQUENCE OF CRANKS (FROM "INDICATOR DIAGRAMS," McGIBBONS)

events are too early then the eccentric must be moved forward towards the crank while if too late, it must be moved away from the crank, unless the gear is indirect in which case the opposite will be the case.

Cards From Compound Engines

Cards taken from compound engines show exactly the same characteristics as those from simple engines, but it is usual to try and balance the load by the aid of the indicator. The division of the horse power equally between each cylinder gives an even turning moment on the cranks, and is very desirable. With compound engines the cranks are in most cases set at 90 degrees, and the H. P. crank leads the L. P. though there are cases where the L. P. leads. There used to be some compound engines with cranks at 180 degrees, but these were fitted with fly wheels and were used for marine works. The sequence of cranks is not of much importance in compound jobs but it is in triple expansion engines. Outside of a few large pumping engines, stationary engineers in Canada are not troubled much with triple engines, and it is hardly worth going into the question of these engines in this course.

The cards shown here illustrate the effect that the sequence of the cranks has in a compound engine. The first shows an engine with the cranks at 90 degrees, and the H.P. leading the LP.. and there is no receiver between the two cylinders. This also has an effect on the cards. When there is no receiver between the H.P. and L.P. then the back pressure on the H.P. rises more as the L.P. cuts off than when a receiver is fitted. There is not the same drop at admission into the L.P. with a receiver as without, owing to the greater volume of steam that the L.P. has to draw from. The difference shown here is that when the H.P. cranks leads the back pressure rises more in the H.P. on account of the angularity of the H.P. rod. There is little difference, however, and the effect is nothing like so much marked as in the case of triple engines. We are indebted for this illustration to "Indicator Diagrams" by W. C. McGibbon, M.I.E.S.

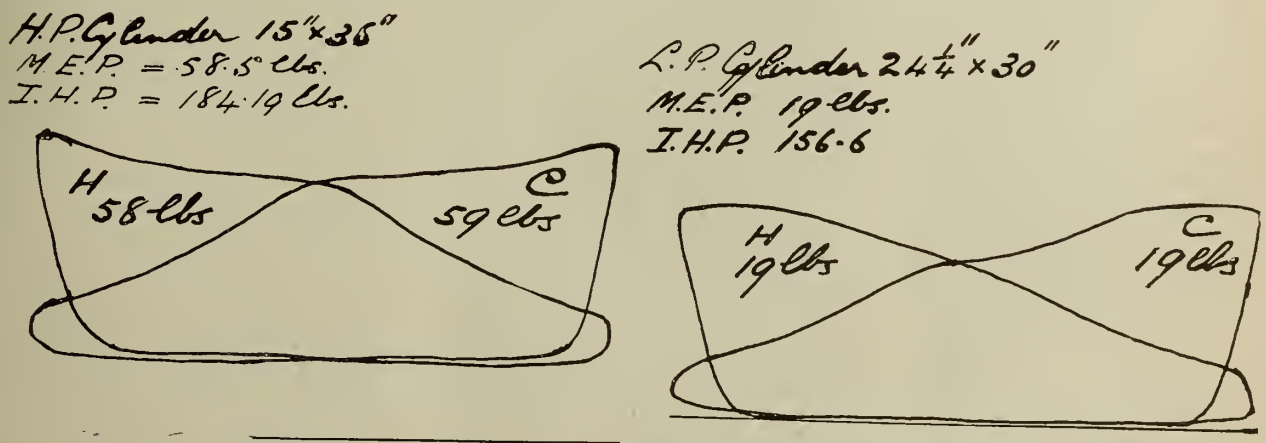
Conclusions.

We have dealt in this course with the subject of indicator diagrams sufficiently far to help out a man going up for examination, and we hope enough to interest him into going farther. The matter dealt with here is but an outline of the whole subject, but for obvious reasons we cannot attempt to deal any more fully with it in the space of this magazine. We have tried to make clear what we have gone into, and feel sure if the reader thoroughly absorbs what has been said, he will be in a good position to satisfy the examiners. For further information there are many excellent text books on this subject, and we would advise the reader who is interested to buy one and study it. The subject of indicator diagrams is a wide one, and full of interest, and the more the operating engineer knows of them the better man he will be.

We have dealt in this course with the main subjects which may be called for in examination, and feel that there is not much to be gained by going further However we should like to hear from those who have been following the articles, and receive suggestions as to what they would like taken up, and the opinion of the majority will decide. There may be portions which some readers would like reviewed, or some point which a reader may not be clear on, and would like to see more in detail. The matter rests with our readers, and we will await their decision.

NEW OXYGEN PLANT

In these days of general industrial improvement it is refreshing to note the spirit of optimism evidenced in the announcement recently authorized, that the Dominion Oxygen Company, Limited, will break ground in mid-July for a new quarter-of-a-million-dollar oxygen plant at Montreal, which will double the company's present capacity. The building will be 100 ft. x 100 ft., and will be substantially a duplicate of the Company's Toronto plant, which until now has supplied oxygen to Canadian industrial users through five district distributing stations. The Montreal plant will be the second of five producing plants projected at the time the company was organized last year.



ACTUAL CARDS FROM COMPOUND ENGINE.

Boiler Accessories from a Safety View Point

The Author Considers the Various Mountings of the Modern Boiler, and Suggestions are Made for the Greater Safety of the Boiler Room Operator and Attendants.

Being without knowledge of the difference between accessories, apparatus, appliances, and fittings, as applied to steam boilers, I have selected a few of those devices which I consider accessories, and have treated each in the order of their seeming importance.

Safety Valves.—There should be at least two safety valves on every steam boiler, for the reason that if only one valve is provided it may fail. It is evident that if there are two or more safety valves there will be less likelihood of excess pressure being raised on the boiler than if one only is used. We are assuming that the combined capacity of the valves is proper and in accordance with modern standards.

The question of mounting the valves on a Y or other base, the single outlet of which connects with the boiler has been frequently debated upon, and apparently there is no objection to the Y-base.

It is difficult to mention safety features of the valve itself which have not already been taken care of by manufacturers of approved valves. When the valves are constructed of approved materials, equipped with the correct spring for the pressure to be carried, and have the desired angle of disc and seat, there is little further to be said, except that there must be an easily accessible means of lifting the disc from the seat for testing purposes, "easily accessible means " to be interpreted as indicating that the attendant must be able to lift the disc from the seat while the boiler is under pressure, without danger of burns on hot parts, without having to grope about for a cord or lever, without climbing a ladder, and, preferably, from a point when the pressure-gauge and the water-gauge glass can be viewed while the disc is being held off its seat. In operating practice it too frequently occurs that the boilers are being worked beyond normal rated capacity, and if the water chances to be quite high in the boiler, the lifting of the disc when the gauge pressure is up to within a pound or two of the blowing point may cause water to be carrid into the steam line. If both the pressure-gauge and the water-gauge glass are visible from the point where the disc may be raised, the action of the water in the glass will very often indicate to the attendant whether the disc should be instantly dropped or whether it is safe to hold it open for a few seconds. Theoretically, the lifting of the disc under any conditions will not cause water to be carried into the steam line, but in practice this frequently occurs. Where the boiler load is intermittent, which is also a frequent occurrence it is often necessary to carry the water very high in the boiler during periods of the lesser steam demands, in order that when greater steam demands are suddenly made it will not be necessary to pump feed-water rapidly into the vessel, thus making it more difficult to maintain the necessary steam pressure.

The discharge outlets of the safety valves should, of course, be so arranged that there will be no likelihood of any person being scalded, or having dust blown into his face and eyes, when the safety valves open, but it is not desirable that the outlet should be piped farther than absolutely necessary. The piping should be as straight as possible and with no more than one bend or elbow in the line. The bend or elbow should be provided with at least a 1in. free drain at the lowest point, except that if the discharge outlet is less than 1in., then the drain need not be so large.There are cases on record where persons have been scalded by safety-valve discharge, and also where severe eye injuries have resulted from dust on the boiler tops being blown into the eyes of attendants. In some plants a ¾in. pop valve is installed on each boiler, and set 2lb. or 3lb. lighter than the main safety valves. The blowing of this pilot valve, which makes considerable noise, is a warning to the attendants that the main valves are about to blow, and I am not sure that it is not a good idea to place pilot safety valves on every boiler, for the expense is not considerable, and there is, no doubt, an advantage in knowing that the main valves are about to blow.

Water-gauge Glass.—It is generally conceded that the gauge glass should be provided with a guard to prevent flying particles of broken glass from striking the attendants, but it is not easy to obtain guards which will leave a free and un-obstructed view of the water level when the water column is located 10ft. or 15ft. above the boiler room floor. This is not an uncommon height on several types of boilers. Gauge glass guards of a suitable and efficient nature are limited to a very few, and unless the purchaser chances to select one of these few, the result is dissatisfaction and the discarding of the guard. Since the breaking of the gauge glass is a common, expected, and unavoidable occurrence, and since many severe injuries have been received from flying particles of glass, it is evident that operators should make every effort to secure a proper guard, and be willing to experiment to some extent in the endeavour to get one which is efficient and at the same time does not obstruct the view of the water level.

The newer forms of connections for the gauge glass permit considerable misalignment of the glass and more expansion than the types heretofore used, so that glasses will be breaking less frequently; but no device, other than a guard around the glass itself, may be expected to eliminate the danger incident to a breaking glass. Until very recently the tightening of the gauge-glass gasket was done by revolving a hexagonal nut. The action of revolving this nut put a considerable twisting strain on the glass. In addition to this valuable form of the ordinary packing gland and follower, and puts no twisting strain on the glass. In addition to this valuable feature, it permits great misalignment of the glass. The only. safe gauge-glass valve is the quick-opening chain-operated type, which permits the operator to stand some distance from the glass and control the line of steam and water to it by merely pulling on one of two chains, either to open or to close the valves as may be required. With the screw type of gauge-glass valve it is necessary for the operator in opening and closing the valve to expose himself to the danger of a glass breaking, and the exposure is for a considerable length of time, since it takes considerable time either to open or to close the two valves.

Gauge Cocks. — The non-thread weighted or self-closing gauge cocks have many advantages over the screw type, and can be used to more advantage in a great number of places than the screw type, the latter being improper for any condition except locomotive work, where the vibration and jar are so great that the screw type is better. The only reason that the self-closing type has not met with more favour is because attendants will not give them the attention to which they are entitled, with the result that they leak. With reasonable care—and it is expected that all mechanical equipment should have this—the self-closing gauge cock will outlast any other, is far safer than the screw type, and the attendants using them are in no danger of being scalded through causes attributable to the type of valve; whereas, with the screw type, scalding is not uncommon. There are cases where the valve was screwed entirely out, thus allowing a stream of hot water to discharge from the valve opening, with no way to stop it except to relieve the boiler of all pressure.

Water Columns.—The columns of many of the older installations are frequently of insufficient capacity, and while, theoretically, water seeks its

own level, it is a fact that the gauge glass frequently shows a false water level where the column capacity is too small, and the installation of a modern type of column and its equipment is a good investment for any boiler-user who may at present be using the older types of small columns, scarcely larger in internal diameter than the pipes to which they connect. Obviously, since the purpose of the column is to show a still water level in the boiler, it follows that it should be of sufficient capacity to ensure the least possible agitation. The difference of opinion as to whether the column connection should be equipped with stop-valves is considerable, but there is scarcely greater excuse for stop-valves on the water-column connections than there is for stop-valves between the safety valve and boiler, and the water-column stop-valves will eventually be closed at a time when they should be open; at least, we are led to that conclusion when we remember that it is always the unloaded gun which kills. It is admitted that there are advantages in having stop-valves on the water-column connections, especially in territories where boiler-feed water is quite bad, for water with considerable solid in it causes accumulations of this solid, whatever it may be in and on the parts of the gauge cocks, with the result that they leak more or less. With the stop-valves in the water-column connections the column may be shut off and the valves repaired without blowing down the boiler. I think, though, that the disadvantages of having the stop-valves outweigh the advantages.

High and Low-water Alarms.—These alarms have their advantages, but they also have their disadvantages. In my opinion they should not be used, for the simple reason that attendants invariably come to rely solely on the automatic action of the alarms, with the result that frequently the water level runs dangerosuly low, through failure of the alarm, and it would seem that the attendant should not have duties sufficiently multitudinous to prevent him from properly watching the water level through the gauge glass and the testing of the gauge cocks.

Pressure Gauges.—These instruments, as a rule, do not cause accidents, and yet, if they are not equipped with a siphon in the form of a loop or U-bend, the tube will shortly harden and cause the gauge hand to show improper reading.

Blow-off.—A common danger which has, without any good reason, existed for many years exists in the use of a 2½in.-diameter blow-off pipe on certain types of water-tube boilers. The type referred to has a drum capacity of about 44 cub. ft., and, under average conditions, the drum would be half filled with water during normal operation —that is, there would be, roughly,20 to 25 cub. ft. of water in the drum. With 160lb. gauge pressure, which is the normal pressure for the type, it is possible to blow all the water out of the drum in between 8secs. and 10secs., which means that even with quick opening and closing blow-off valves the attendant would have great difficulty in properly blowing the boiler down without blowing out so much water as to leave the drum and certain of the tubes empty and exposed to the hot furnace gases. It is strange that the manufacturer, the user, and the multitude of inspectors do not realise this danger and reduce the diameter of the blow-off thus create a dangerous condition. Our boiler codes give us the minimum and maximum diameter of the blow-off pipe without taking into account the cubical capacity of the boiler. The size of the blow-off equipment on fire-tube boilers is seldom found to be too great. Attendants soon learn that they cannot, with safety, open the blow-off valve wide when blowing down, so they adopt the practice of opening it only part way, the result being that proper blowing down is not accomplished, and sediment lodges in the valve, causes various inconveniences, expensive repairs, and danger.

It seems desirable that the code should take into account the proper area of blow-off pipe with relation to the pressure carried, and the cubical contents of the boiler between normal water level and the lowest safe water level.

Non-return Valves.—Among many pipe to 1½in., which would be ample for the particular type referred to. A boiler with less than 75 cub. ft. of water between the point registered by the centre of the gauge glass and the highest point of contact with the furnace gases, and carrying a pressure of 160lb., should have a blow-off pipe no greater than 2in. in diameter. With any larger diameter the proper blowing down of the boiler will lower the water level to below the highest point of the gases and dangerous practices continually going on, at least two stand out. While they are not related to each other, they seem to exist pretty well together in power-station work. The one is the synchronising of two alternators by guess— that is, by watching the effect of the current alternations on an incandescent lamp. The other is the cutting in of a boiler on a header which is being supplied by other boilers. The guesswork on synchronising not infrequently throws the whole system out of step, and the guessing of the proper time to open the stop valve from boiler to header sometimes results in disastrous explosions. In the first case, a very simple and inexpensive synchronising indicator is purchasable and reliable. In the second instance, a much cheaper and simpler device, in the form of a non-return valve, is procurable which will not only prevent the boiler from being cut into the line too soon,but will protect the entire system in the event of a tube bursting in one boiler. Non-return valves are a necessity, but education of the user into the necessities of having non-return-valves is an inordinately slow process. If it is not beyond the jurisdiction of the boiler to deal with non-return valves, then certainly the code should be used on every boiler connecting to a header with one or more other boilers.

Rotary Tube Cleaners.—Rotary tube cleaners, motor or turbine driven, are the only mechanical means for cleaning the interiors of tubes of water-tube boilers. With curved tubes, the cleaner, in its effort to follow a straight line through the curved tube, more or less rapidly wears away the metal of the tube at certain points near the bends, and not infrequently the tubes are so thinned by the cleaner that they burst during operation. There is no object in running the cleaner through the tubes until there is some scale present. The greater the amount of scale the slower the cleaner will travel through the tube, and, since the rotary speed of the cleaner is constant, it follows that if it stands still, or practically still, at any one point in the tube, and its cutting parts continue to revolve, a spot in the tube will be worn by the cutters. The extent of this wearing cannot be determined by any process of inspection; therefore a danger is present, the character of which makes it highly advisable that the boiler washer be most carefully instructed in the proper use of the cleaner, having the dangers of improper use explained to him, and further advisable that tubes which are apparently still good should be cut out at certain intervals, depending upon the frequency of the use of the cleaner, and replaced with new ones; the old being examined to determine the remaining thickness. Steam-turbine cleaners have an added danger of the steam hose bursting, and this hose, in addition to being wire-wound, should be discarded and replaced with a new one at least twice each year, regardless of the amount of actual use, for both the rubber and the fabric used in the manufacture of the hose deteriorate with age, and bursting steam hose has caused a great number of very serious accidents.

Concrete Floors Under Boilers.— If concrete floors are not accessories, they nevertheless deserve comment when they form the bottom of the ashpit and combustion chamber of any type of boiler, in localities where the atmospheric temperature reaches or falls below the freezing point. A substantial concrete floor laid on clay, or almost any soil other than dry sand, becomes dangerous when heated through to a temperature of more than 212 degrees F., for the moisture which collects under the floor is converted into steam by the heat, and there is probability of the floor being burst with great violence, due to the pressure under it. There are records of

accidents resulting from what amounted to an explosion of the floor, caused by steam pressure forming under it, and, quite naturally, before a substantial floor can be burst by steam pressure, acting upward under it, pressure must be quite high; it just as naturally follows that this high pressure, when instantaneously released,must be expected to do considerable damage in the immediate vicinity.The specifying engineer of boiler installations should, therefore, take into account the dangers connected with the use of concrete floors under boilers, when such floors are laid on soil which will not permit any steam formed under the floor to travel downward before the pressure generated reaches anything substantially above atmospheric.

Furnace-door Locks.—There have been a number of accidents to boiler attendants, in the nature of scalds and hot-fuel burns, resulting when bursting tubes or flues push open the fire or ashpit doors and allow steam and live coals to pass into the boiler room, at a point where the attendant may be expected to be stationed. A great many, if not all, of these accidents could have been prevented by the installation of automatic door-locks, types of which are now on the market, and which, when the doors are even somewhat carelessly closed by the attendants, still lock, so that no amount of pressure inside the furnace or ashpit will throw the doors open. The objection to installation of locks is frequently that if the lock is so substantial that it will not break and allow the door to open, then the pressure which would, without the door-lock, open the door and be relieved, must then blow out the boiler walls. The proper attitude, however, is to consider that the safety of the attendant is the first consideration; if it is necessary to sacrifice a part of a boiler wall to save the attendant's life, then the wall should be sacrificed. It does not follow, however, that the boiler walls will be blown out by a tube explosion, in the event of the furnace and ashpit doors being locked, though admittedly, if a 4in. tube in a water-tube boiler carrying 160lb. pressure, burst along 1ft. or 2ft. of its length, there will momentarily be a considerable pressure in the fire and gas passages; this pressure may, if the doors are locked, blow down a portion of the boiler walls or lift off the top cover. There are perhaps no more than one or two inexpensive, yet reliable, door-locks manufactured, and the reluctance of the operators to install locks is caused to some extent by the failure of some of the makeshifts which have been installed, but all of those having opportunity to do so should prevail upon operators to install approved furnace- and ashpit-door locks.

Steam-flow Meter.—This valuable device has not met with the welcome reception to which it is entitled, and there is probably no good reason why every boiler operating in a battery with one or more other boilers should not be equipped with a steam-flow meter which will be a positive indication to the fireman that each boiler is, or is not delivering through its steam line its proper proportion of steam.

In any battery of boilers, even when each boiler has precisely the same theoretical capacity as its fellows,there will be one or more either delivering less steam or more steam than it should deliver, and this inefficient and rather dangerous condition is instantly detected by the reading of the steam-flow meter. The increasing or decreasing of the fire intensity can immediately be accomplished to exactly the degree required for the boiler to do its proportion of steaming. Perhaps the safety features of a steam-flow meter are greatly outweighed by their efficiency features. Nevertheless, there is less danger present in the operation of a battery of boilers when each boiler is doing its proper portion of the work than when one or more boilers are doing much more or much less than its share of the work; the danger lying in the probabilities of burning the tubes or sheets of the boilers which are over-fired, and the danger of low water in the same boilers and excess water in the under-fired boilers. These statements do not take into account the ideal condition of boiler operation, which is seldom realised, but instead contemplate average working conditions where some scale is present and where all boilers are fed through a common source.

Oil Burners.—All steam or air atomised oil burners are in themselves dangerous or the equipment necessarily used in connection with them becomes dangerous through their use. Mechanical atomisation is reasonably safe. Since mechanical atomisation is more economical, by a considerable margin, than steam or air atomisation, it may be expected that sooner or later all atomisation will be done by mechanical process to the complete exclusion of the steam or air process. The most economical steam atomiser oil burner will require from 2 to 4 per cent of the steam generated in the boiler for atomisation of the fuel oil, whereas mechanical atomisers use none of the power generated by the boiler,exclusively of that required to pump the oil to a given pressure and furnish heat for it, and this power is also required with the steam atomiser. With steam atomisation, carbonisation takes place at the burner tip resulting in an unequal spread of the fire, and this, in addition to reducing efficiency, produces a danger, in that it frequently causes the fire to concentrate upon one or more relatively small areas on the tubes or sheets, causing burns and bags.

This condition does not exist with mechanical atomisation. The steam or air atomiser will be set to atomise the oil properly at a given boiler pressure, which, let us say, is 10lb. lower than the desired boiler pressure. The attendant regulates the burner to increase the boiler by 10lb. The multitudinous duhim to some refractory boiler-feed pump, or elsewhere, and while he is busy for five minutes the steam on the boiler increases the desired 10lb., with the reties of the average attendant call sult that the atomiser valve will pass more steam to the burner than is desirable, and literally blow the fire out. After a few seconds, a quart or more of crude oil has entered the furnace, and since there is no flame present, the hot bricks generate explosive gas from the oil. The gas explodes.

Such a condition is altogether unlikely with mechanical atomisation. The one possible objection to mechanical atomisation is the necessity for bringing the oil to a high temperature before it enters the burner. The temperature is necessary to reduce the oil from a heavy to a light condition, and it seems to be the practice to heat the oil to 250 degrees or 275 degrees F., yet I have learned of no accidents attributable to bringing the oil to a Fahrenheit temperature of 275 degrees. Careful damper regulation is paramountly necessary when oil fuel is used. If the attendant is burning coal and forgets to open the damper before firing-up after a short or long shut-down, there may or may not be an explosion of confined coal gas, but with oil fuel it is extremely dangerous to start the fire or admit any oil to the furnace until after the damper may have been opened at least a few seconds, for fuel oil is converted into gas very quickly by relatively low temperatures, and the explosive power of the gas is considerable, so unless the damper is opened wide before oil is admitted to the furnace, an explosion of violence is apt to occur, and not merely blow down a portion of the boiler walls, but injure the attendants.

Explosions of Gases in Fireboxes.—Burns from hot gases passing through the furnace doors into the boiler room are rather too common. These burns are not always caused by explosion of furnace gas, but the person burned and those who may make a perfunctory examination into the case are apt to state that there was an explosion of gas in the furnace.

If a boiler is manually fired and has a thick, long flame, the fire burning with a strong draught, and if, for any reason, the damper is suddenly closed, hot gases and the flames themselves frequently pass through the furnace doors in the fire room, and any person in line with the fire door, and no more than 3 ft. or 4 ft. away from it, is apt to be burned, whether he is actually attending to the fire or whether the door was closed.

The sudden closing of the damper is something which does not frequently take place accidentally, although there are one or two types of damper regulators, which, under certain conditions of bad repair, permit a rather rapi

closing of the damper. None of these regulators, if in good repair, will close the damper rapidly enough to cause flame and hot gases to pass into the boiler room.

Many of the burns from hot gases which pass into the fire room through causes other than the furnace explosions, have been traced to the sudden closing of a manually operated damper, weighted in a manner to hold the damper closed, and it is good practice, therefore, to weight a damper in such a manner and so heavily that the damper will open itself. When this is done, danger of the damper accidentally being closed is very slight, and any one of many simple contrivances can be arranged to hold the damper in the closed or any intermediate position against the tendency of the weight to open it.

If a shovelful of very wet coal and as much as a quart of free water is thrown upon a red or black fire, a considerable explosion is apt to result from the water gas which is instantly formed and ignited, so evidently it is bad practice to stand in front of the furnace door and throw in wet coal and unabsorbed water.

If the damper is partly closed, as is frequently the case in normal operation, to prevent too rapid combustion, any exploding gas in the firebox will be more dangerous to the attendant in front of the fire doors than the same amount of gas would be with the damper wide open.

Where the steam blowers are used for forced draught, there is generally considerable piping between the original source of steam and the blower valve. If the blower is not in constant use, condensation takes place in the supply pipe and considerable water accumulates. The opening of the blower valve permits the water in the pipe to be suddenly projected into the ashpit, where the temperature, under many normal conditions, may be well over 225 degrees or 250 degrees F., and while I am not prepared to say why the explosion should take place in the ashpit, it nevertheless is a fact that this has occurred, burning an attendant severely. Although it may seem that to install a steam trap immediately above the blower valve is an over-precautionary measure, there is at least one case on record which would seem to justify such an installation.

I do not personally know of any instance where the attendant was burned when he opened the furnace door at a time when forced draught was being caused by a steam blower into the ashpit, but I have heard of such cases, and believe they occur. The precaution of providing an interlocking device on the furnace door which will shut-off the blower before the door can be fully unlatched, and which I understand has been adopted in some of the plants of the Du Pont Company, is a valuable one, and its value should undoubtedly be brought to the attention of every user of forced draught, whether the draught is caused by a steam blower or a fan. It is conceivable that the arrangement could be cheaply and satisfactorily installed, and, as long as it was kept in order, would positively prevent the evident danger.

It is thought by some, and I believe not without basis, that the opening of a furnace door, and the resultant admittance of air to the firebox, cause explosion of gases which have accumulated in the space above the fire, even though the damper may be open. It is difficult to see how any considerable quantity of gas would accumulate and remain in the firebox when the damper is open; yet, apparently, such conditions have existed.

A good many householders who burn coal in some sort of furnace, such as the hot-air type, will have at some time noticed that after filling up the furnace with fresh coal for overnight banking purposes, all flame disappears, and in 5 or 10 mins., if the furnace door is opened and a rush of air is caused to enter the furnace door by fanning across the space with a newspaper, or even by blowing into the furnace, there will be a sudden burst of flame up through the coal. While it is not in the nature of an explosion, it is conceivable that if the fire area were large, as it is in the case of steam boilers, and the quantity of coal proportionately large, then the sudden bursting into flame would take the appearance of an explosion.

The only safety measures which suggest themselves to me in connection with prevention of furnace gas explosion, or injuries resulting from unpreventable explosions are, first, the providing of a proper latch for the furnace door, and, second, the careful education of the firemen in how to perform their duties.

*Paper delivered before the Engineering Section of the National Safety Council at Philadelphia.

A BRITISH DISCOVERY RE-DISCOVERED

Great interest was caused recently in London by a demonstration, given before the Institution of Electrical Engineers, of a strange phenomenon alleged to be absolutely new to science. When an electric current is passed through a half-conducting material, such as lithographic stone, in close contact with a metal, the metal and the stone stick together with a force which is out of proportion to the strength of the current passing from one to the other. The demonstrators, who came from Scandinavia, showed how this phenomenon could be applied in making a loud-speaking telephone. By its help they made a violin reproduce music played in a distant room and "speak" words spoken into a distant telephone transmitter. This demonstration was, however, followed very soon by proof that the phenomenon had been discovered many years before in Great Britain and its application to telephony had actually been described before learned societies and in a popular encyclopedia. The discovery in Scandinavia was therefore a re-discovery and the incident suggests that the past records of British research and invention may contain more hidden items capable of practical development in the light of the fuller knowledge now available.

AN ALL OIL NAVY

Naval experts and shipbuilders in all parts of the world have been impressed by the decision of the British Admiralty to build only oil-burning ships in future. Many reasons have combined to bring about this decision. Among them are the convenience of transporting oil and storing it at strategic points, the small space which it occupies on board ship, the ease with which oil may be taken on board ship from tanks or tank steamers, the simplification of stoking, and the high efficiency of the fuel. It is calculated that even at present prices oil is cheaper than coal as a fuel, apart from the other economies enumerated. This official decision is likely to give a fillip to the movement, already taking place rapidly, for the conversion of large liners and other merchant vessels flying the British flag from coal-firing to oil-firing. One benefit of the change will be to do away with the terrible conditions to which stokers on coal-fired ships are subjected, especially on tropical seas. On humanitarian grounds alone the example of British enterprise in this direction is worthy of world-wide adoption.

To every user of engines driven by crude oil, the process of starting is a nightmare. The blow lamp by means of which the fuel spray is usually given its initial heat, is a device with an almost Satanic cussedness of behaviour. Moreover its use involves a considerable amount of time as well as trouble. Consequently there ought to be a wide welcome for an ingenious electric heater developed by a leading British firm of oil engine makers. The device is extremely simple. It consists essentially of an electric heating element of high resistance wire placed in the line of action of the oil spray. A small amount of current suffices to make this wire white hot, in which condition it brings the spray rapidly to the temperature required for starting. After the engine has gone ahead the element is withdrawn, so that it is not exposed for more than a minute or so to the high temperature of the combustion chamber,—an arrangement which gives it long life and great reliability. The electric current required for operating the heater is supplied by a 4-volt or a 6-volt battery charged from a tiny electric generator, driven through a belt from the engine. By means of this device the engine can be quickly started up from cold without the slightest trouble. Twelve months trial of the apparatus has shown it to be thoroughly satisfactory.

Overhauling and Adjusting in the Engine Room

Following the Course of Previous Articles, in This Instalment the Valve Gear of the "Cameron" Pump is Illustrated and Described. This Gear Has Some Good Points Which Are Defined.

By "FITTER"

IN THE last issue of "Power House" we illustrated the steam valve and gear of the Darling pump, and we now take up another simplex type of pump also made in Canada, and employing a different method of operating the steam valve. The principle is of course the same in all simplex pumps, that is the main valve is moved from side to side by an auxiliary valve, but the method of moving the auxiliary valve varies in different pumps.

The Cameron Pump

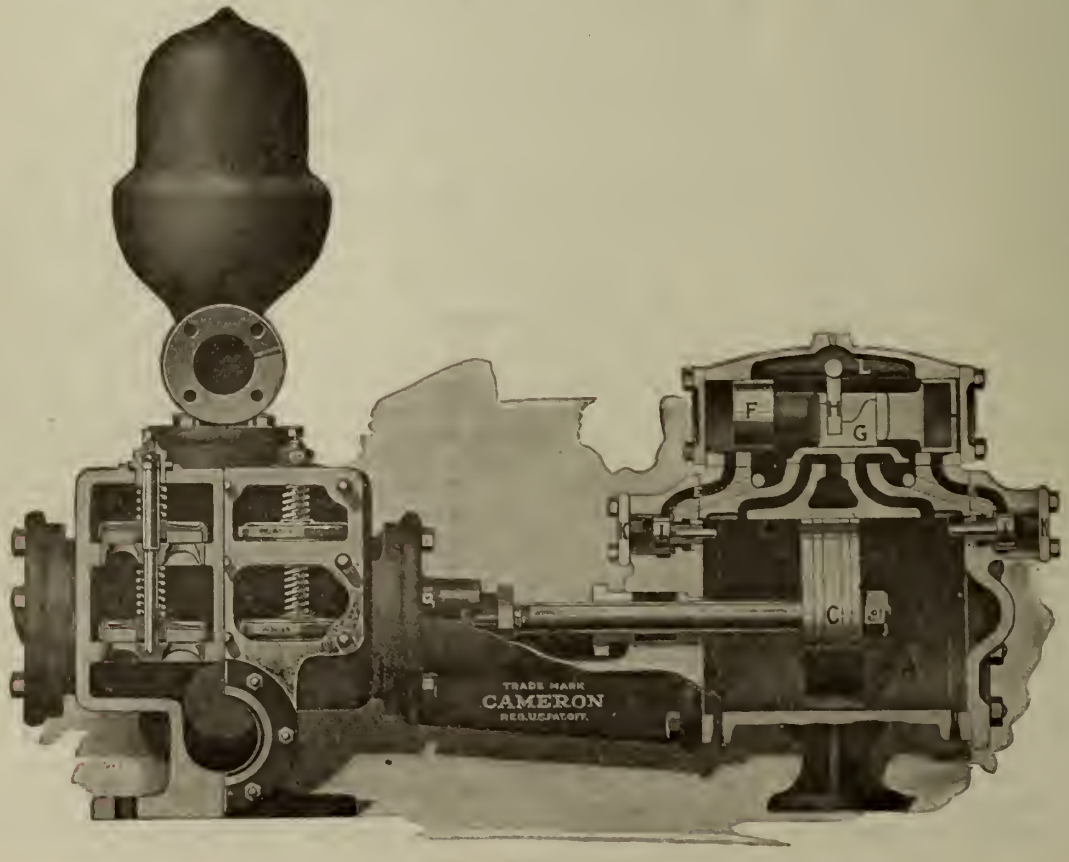
The "Cameron" pump is illustrated in the accompanying cut, which shows very clearly the method of operating the valve. In this case there is no spool on the rod, and no spindle projecting from the valve chest, and no levers of any kind on the outside of the pump.

Referring to the cut, it will be noticed that the slide valve G is of somewhat different construction to the ordinary slide valve, there being a division in the centre, which performs the function of closing the exhaust cavity off from the steam port as the valve moves from end to end. Looking above the slide valve, the auxiliary valve F is shown partly in section and partly in elevation. This enables us to observe plainly the construction of this valve. It is really formed like a piston valve, the ends of the piston being hollow, as can be seen having a small outlet as shown. The hollow piston being filled with steam the steam escapes through this small outlet and fills the clearance space between the valve and the valve chest cover with steam, thus making the valve in a state of equilibrium, with no tendency to move in either direction.

Referring again to the cut, it will be noticed that there are two small pistons or plungers at each end of the steam cylinder marked I I, and that the spindles or rods of the small pistons project into the steam cylinder. These pistons are covering when in their normal position the port E at each end of the cylinder and these ports communicate with the chest in which the auxiliary valve is working. In addition to these ports E, there can be seen two smaller ports which are shown in dotted lines, and which lead from the main steam chest to the back of the small pistons I I and thus tend to keep these pistons always over the ports E E. The side valve G is attached to the auxiliary valve by a lug which causes the slide valve to be driven in the same direction as the auxiliary valve. This lever H extends through the steam chest, and on the outside of the chest a handle is attached, which enables the auxiliary valve to be moved by hand before starting up the pump, or for placing the piston in a desired position.

The Operation

The operation of the valve can now be followed from the illustration. Looking at the cut we see that the piston is receiving steam at the back side and is therefore moving on the out stroke, or towards the water end of the pump. The other side of the piston is open to the exhaust through the slide valve G. The auxiliary valve is at the extreme end of its stroke towards the back end of the cylinder, and in this position the port E is covered by the hollow piston, of the valve, and also by the small plunger I. so that it is completely closed off. At the other end the port E is closed off by the plunger I alone. As the piston goes forward, and approaches the end of its stroke it will come in contact with the rod or spindle of the plunger I forcing it forward against the pressure of the steam and opening the port E. to the cylinder, which is in communication with the exhaust. The result is that the steam in the clearance space between the end of the auxiliary valve and the auxiliary steam chest cover, is exhausted, which



THE CAMERON PUMP

causes an excess of pressure on the other side of the valve, and it is thrown over to the opposite side of the chest taking the slide valve G with it and thus reversing the motion of the piston. This is an absolutely positive action, and the reversal of motion is absolutely bound to occur when the piston touches the small plunger I, which is called the reverse valve.

The reverse valve spindle is made sufficiently long to ensure a certain amount of steam being retained in the cylinder to allow for cushioning, and it will be noticed that before the piston reaches the reverse valve it has already covered the main opening of the exhaust port, though there is still a small orifice left to allow the steam from the port E to escape. Thus the piston performs its own cushioning in this as in most pumps, and the motion of the auxiliary valve is also controlled by the same principle. The piston end of the auxiliary valve as can be seen covers the port E before the valve reaches the end of the clearance space.

Maintenance.

It can be clearly seen that in this motion there are a minimum of moving parts, and great simplicity in the port castings. The only moving parts are the auxiliary valve F, the main valve G, and the two small plungers I I. There is but little wear, as the movement of the valves is very slight, they being at rest during a portion of the stroke, while the auxiliary valve moves with a minimum of friction. The absence of valves spindles protruding through the chest makes less glands to be packed than are usual the only gland being that on the main piston rod. The cut shows plainly the construction of the water end of the pump. These pumps have been used largely in mining work as well as stationary practice.

Universal Craftsmen's Council of Engineers

This Body of Stationary Engineers Who Are Also Members of the Masonic Order, Will Hold Their Convention From August 2 to August 6 in Toronto, at the King Edward Hotel.

TORONTO has been chosen as the scene of the 19th annual Convention of the Universal Craftsmen's Council of Engineers, a body composed of engineers who are also members of the Masonic Fraternity. The organization is a strong one in the United States and is a growing one in Canada, there being two councils in Toronto, one in Hamilton, which was recently formed, while the cities of Winnipeg and Brandon each have one. Montreal is expected very shortly to be added to the list of Canadian centres of this order.

Needless to say, there has been a vast amount of work in connection with this convention, and it has been handled in its entirety by the local committee, the chairman of which is Mr. L. J. Cudbird, Chief Engineer of the Toronto City Hall, and a Past Worthy Chief of the Toronto Council. He has been assisted in his efforts by the following committee:—

Harry Parker, D. D. G. W. C., Canada S. S. Lines—H. Potter, P. W. C., Hinds & Dawsch—W. Wolfenden, W. C., City Hall—J. Grimshaw, Administration Bldg. B. O. E.—W. Pike, King Edward Hotel—Geo. Aldridge, Bowser Pump Co.—R. Allman, W. C., Technical School—H. E. Terry, P. G. W. C., Continental Life Building—A. M. Wickens, D. D. G. W. C. Consulting Engineer—W. J. Hudson, P. W. C. , Coco Cola Co.—T. C. McAree A. C., Toronto Electric Light—Chas. Holmes, Boiler Inspection & Ins. Co.—L. Westwood, Prince George Hotel—Alex. Auchterlonie, Sick Children's Hospital, Wm. Watt, P. W. C., Swifts Abattoir.

The Power Exhibition

One of the features of the convention will be an exhibition of power plant supplies and accessories, and the following firms have secured space at the time of writing.—

Beldams Canadian Asbestos Co,	Booth 54
Crouse Hinds Co. of Canada Ltd	22
James Morrison Brass Mfg. Co.	28
Chapman Ball Bearing Co.	33
Canadian Jones Manville	
Kirby & Co.	17
Demco Machine Tool Co.	
Refinite Co. of Canada	
Superheater Co. of Canada	1 & 7
S.K.F. Ball Bearing Co.	2
Valve Engineering Co.	3
Otis Elevator Co.	6
Canadian Sirocco Co.	14
Republic Flow Meters	15
Engineering Specialties	4
Dearborn Drug & Chemical Co.	19
Jenkins Valve Co.	20
Underfeed Stoker Co. of Canada	24
C A. Dunham Co.	25
Powers Regulator Co.	26
J. H. Wenting	27
Crane Valve Co.	30
Allen General Supplies	37-8-9, 43-4-5
Wilson Packing Co.	42
Darling Bros.	55
W. R. Sexton	56
Taylor Instrument Co.	64
Lunkenheimer Valve Co.	67
Garlock Packing Co.	65
McColl Bros.	68
Hollow Centre Packing Co.	69
POWER HOUSE	70
Imperial Oil Co.	29
Black Donald Graphite	58
W. Cunningham Co.	13
Canadian Blower & Forge	31
Pierce Fuse Devoe Switch	21
Taylor & Arnold	34
Home Rubber Co.	9
Keystone Grease	53

The Entertainment Programme

A most interesting round of entertainments to vary the monotony of business has been arranged and it will be seen from the accompanying programme that neither trouble nor expense has been spared by the committee to ensure the visitors and their ladies having an enjoyable time. The programme is planned in such a way that all those attending will have an excellent opportunity to see the good points of the city. The space in which the exhibits will be shown ensures the best possibility of showing off the various accessories, and the visitors are enjoined on the programme to visit "Exhibition Hall,, The following is the programme in detail:—

Monday, August 1st

Informal reception of Delegates and Visitors

Tuesday, August 2nd

10 a. m.—Invocation, Rev. F. E. Powell.
Official Welcome by Chairman L. J. Cudbird and Chairlady Mrs. H. E. Terry.
Mayor of Toronto
Masonic Fraternity, R. W. Bro. E. M. Carleton.
Board of Trade, R. C. Harris, Com. of Works.
Noon—Opening Session of Grand Council.
1 p. m.—Opening of Exhibition
3 p. m.—Business Session.

Wednesday, August 3rd.

9.30 a. m.—Business Session
2.30 p. m.—Business Session
6.00 p. m.—Automobile Ride. Cars leave City Hall steps. NOTE—Those missing Auto Ride, take King Car to Sunnyside.
9 to 12 p. m.—Dance, Sunnyside Pavilion

Thursday, August 4th

9.30 a. m.—Business Session
2.00 p. m.—Picnic, Island Park. Games, Baseball, etc.
4.00 p.m.—Official Photograph at Island Park.

Friday, August 5th

11.00 a. m.—Memorial Services.
3.00 p. m.—Installation of Officers. Closing Session
8.00 p. m.—Banquet, King Edward Hotel.

Saturday, August 6th

SEEING TORONTO

The United States Gauge Co., New York, have issued their Catalogue No. 50 describing their complete line of pressure gauges for all purposes. Besides gauges of the usual type, vacuum gauges, tire testers, thermometers, and precision instruments in general are described and illustrated.

Member of the Audit Bureau of Circulation

THE ENGINEER IN THE DOG DAYS

WHILE the general public is going around mopping its perspiring brow and groaning about the heat, it is very doubtful if any of them ever give a thought to that portion of its people whose daily lives are led in what might be called zones of high temperature. Among these are the engineers in charge of the various steam power plants, in factories, office buildings, institutions etc. There is a great variation between plant and plant depending on whether it is on the ground level with ample window and door openings, for the circulation of air, or if it is situated in a basement with little natural light and less ventilation. There are any amount of engine rooms through the country where the temperature in these days will be from 100 degrees to 110 or higher, where men carry on over long shifts without fuss or complaint, merely taking things as they come. The casual visitor from the office who has occasion to go down to the engine room in these days, generally leaves it in a hurry, and goes back to his desk with the fan blowing on him, where he has been complaining of the terrific heat all day. The engine room staff must make their own repairs and keep the plant going, regardless of heat, and the fireman must stand in front of his fires and go through the soul roasting task of cleaning whether the thermometer is at 70 degrees or 100. The strange thing is that the average manager or head of a factory, while very much concerned about the comfort of the producing workers in the factory, rarely if ever gives a moment's thought to the comfort of those who are keeping the whole works running. In fact we are sorry to say that it has been our experience, that it is a matter of the greatest difficulty to secure small concessions or relaxations of rules for the benefit of the power plant staff during hot weather, and when such are granted it is with a very grudging spirit.

We would recommend those in authority in factories, institutions, etc. where there is a power plant to pay it a visit for a half hour or so on one of these hot days, and consider how they would like to spend a long day in that atmosphere, and perhaps return at night to do some job on top of the boiler, where the air is too hot almost to breathe. These things are all in the day's work for the stationary engineer, and he does them uncomplainingly, but we know there are moments when he would like to think that the powers that be realised the conditions under which he has to work. Very often these conditions could be much improved for a small expenditure, and this is where the management comes in, the improvement depending on the extent of the interest the management take in the comfort of their power plant staff.

A USEFUL INVESTIGATION

THE University of Illinois, which has done some valuable work through the medium of its Engineering Experiment Station, is now engaged on an investigation of the hot air furnace and system of heating. This is being carried out in co-operation with the National Warm Air Heating and Ventilating Association, and should be productive of good results. In order that the results obtained from the experiments should be of use in practical problems, a plant has been built which operates under the exact conditions found in the ordinary hot air heating installation. The objects of the experiments are to determine a proper method of rating hot air furnaces, so that the proper size of furnace can be definitely selected for the service required, to determine methods of increasing the efficiency and capacity of furnace heating equipment, and generally to determine all unknown factors in connection with this type of heating plant.

There is no country in the world where more interest should be taken in domestic heating plants than in Canada, where they are very much in evidence for the greater part of the year, and where the householder has to go deep into his bank account every year, to purchase indifferent coal which he feeds to an inefficient furnace. Then if the weather gets really cold with a high wind he shivers anyway.

We have never been in a house in this country in the middle of the winter yet that was comfortable, and whether this was due to the bad building or the poor heating system or both, the effect was the same.

Most hot air furnaces are put into houses in a happy go lucky spirit, and very often they are cut down by the contractor as small as he possibly can, in order to save a bit more money. The actual requirements from a scientific point of view we do not beleive are ever considered. The result is a gross waste of fuel, without any degree of comfort, and if the experiments now going on can determine an absolutely correct way of determining the capacity of furnace required, and also a method of rating which will ensure the purchaser getting that capacity, the benefit to the people in general will be enormous. If in addition to this, the most efficient way of carrying piping from basement to rooms, the correct position of register, and the right type of insulation are determined, there will be a large saving in fuel consumption, and the money thus saved to the country will be available for investment in Canada, instead of being eaten up by U. S. exchange and freight charges. The house heating plant in its individual capacity may not look much, but multiplied by the hundreds of thousand of families that use them, it is an exceedingly large factor in the country's expenditure. When we consider that of the money spent thus for fuel, the householder gets probably 20 per cent of its value in heat, he should be interested in anything that tends to improve matters, along these lines.

TORONTO NO 1. C. A. S. E.

A meeting of the above Lodge was held in the Lodge Room Temple Building on July 13th at 8 P. M. Following the usual business of the lodge, and the initiation of two new members, the lecture on Green's Economiser which had been postponed from the last meeting, was given. Notwithstanding the hot weather, and the uncomfortable temperature of the Lodge room, a fair number of the members stayed to hear the lecture, and evinced their interest by the questions they asked at the conclusion of the talk.

Progress in New Equipment

NEW IDEAL PUMP GOVERNOR.

The Ideal Pump Governor, well known in marine circles, has been redesigned. It is now manufactured solely by the Atlas Valve Company, Newark, N. J., whose designing engineers are responsible for the improvements made.

Figs. 1 and 2 show the two principal designs, called Style "A" and Style "B" respectively. Both of these are made for turbine or reciprocating steam-driven pumps. Both styles, also, are approved by the National Board of Supervising Inspectors of Steam Vessels and by the Bureau of Engineering, U. S. Navy Department. Style "A" (Fig. 1) is designed for constant or fixed pressures, whereas Style "B" is made for pressures that may be varied from time to time.

Style "B" (Fig. 2) is equipped with an emergency control lever which provides means for manually operating the governor so that it can be held wide open or be shut off tight, regardless of the pump pressure. Where the pump must deliver an exceptionally high pressure during an emergency, or where pumps must be shut down quickly in case of fire or rupture of the pipe lines, it is evident that this lever adjusting feature is important. It is ready at all times to throw the pump in or out of service as the emergency may require.

This pump governor is of the variable pressure type which can be adjusted to maintain any predetermined pump discharge pressure. At the same time by manipulating the lever an almost instantaneously increased discharge pressure is effected.

The Ideal Governor is piston actuated. It is extremely sensitive, with a patented exclusive feature of an actuating piston operating in a bath of oil. This body of oil not only lubricates the operating piston, but also prevents the liquid being pumped from entering the control cylinder, thus eliminating any possibility of the sticking of the piston due to corrosion, sediment.

The Ideal Governor is very simple in construction and consists of only two moving parts—the steam valve which moves backward and forward within the valve body (which is of the double seated balanced valve type), and the control piston which moves backward and forward in a bath of oil within the control cylinder. There are no diaphragms, cup leather packings or small delicate parts to get out of order.

These governors are installed in the feed line to the pump in a manner as indicated in Fig. 3. Fig. 3 shows Style "A" in place, hence the pump is a constant pressure pump. The control cylinder of this governor is connected through valve "A" and a pipe line to the pump discharge as plainly shown in Fig. 3.

For general use, from three-eighths to two-inch sizes, these governors are made of bronze throughout and for larger sizes up to six-inch they are given iron bodies, trimmed with bronze. For superheated steam they are furnished with steel bodies and monel metal seats and stems.

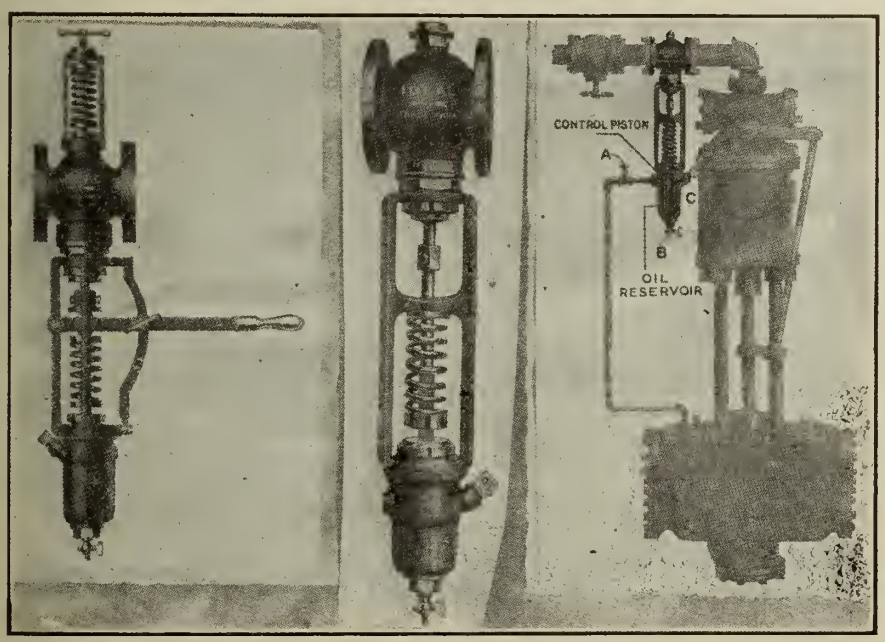

FIG 2 FIG 1 FIG 3

THE PERFECT WIRE ROPE

To a large extent the user of wire ropes must take them on trust—or, at least, on the faith inspired by the maker's name. And few of them can have any notion of the elaborate and detailed care taken to ensure that a wire rope will not murderously betray the men depending upon its strength at sea, in mines, or on constructional work. The policy adopted by one of the leading British makers of wire ropes will, however, serve to illustrate the fact that there is much more in a wire rope than meets the eye. To begin with, the firm produces all the component parts of the rope from the raw materials in its own factory. It therefore has direct control of everything from A. to Z. The steel for the wire is made in the firm's own steel works and is carefully tested to make sure that it is of the exact quality required A sample of every "melt" of steel is chemically analysed, and the analysis is filed so that the makers know the precise composition of the steel in every piece of rope that goes out of the factory. All the wire is drawn from steel which passes the test, and it is carefully galvanized. In the laboratory photographs are taken under the microscope to reveal the structure of every piece of wire. Before any coil of wire is used for rope making it has to go through rigid pulling, bending and twisting tests, winding up with a test in which a length of wire is made into a snarl and straightened out again and again until breakage takes place. Many wire ropes have a hempen core to give them greater flexibility, and in making this core the same patient care and supervision are exercised.

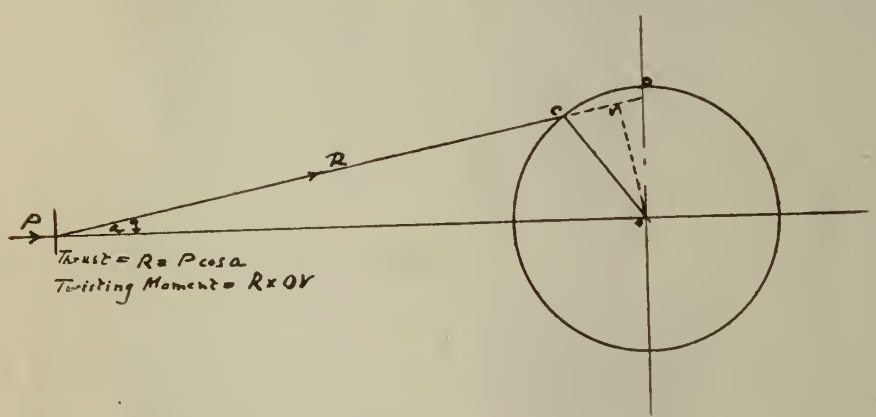
OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

THRUST IN CONNECTING ROD

Mathematics is conceded to be an exact science, and in its application to engineering problems it has need to be, as a good deal depends on it.

In the Question Box for Jan. 20 it is stated that the thrust on the connecting rod equals the total pressure on the piston rod x cos. ang. When the crank is off the centre this would make the thrust on the connecting rod less than the total pressure on the piston. In the Question Box of Feb 20. the thrust in the connecting rod is again stated to be less than the total pressure on the piston. In the Question Box of March 20 is a diagram which might represent the connecting rod crank and centre line of an engine with the crank at right angles to the centre line, and on the opposite page is a statement that "Power House" solves the problem.



SHOWING THRUST IN CONNECTING ROD

The diagram in question forms a right angle triangle and it it stated that the hypotenuse is greater than either of the two sides, which seems to me to be correct, but it differs from the statement made in the other two cases. In graphic statics we are taught that lines may be used to represent forces in both direction and magnitude and if the lines can be arranged to form a closed figure the forces will be in equilibrium, and any side of the figure will be the equilibriant of all the others. If this is true we may represent the forces in the connecting rod crank and piston as in Question Box of March 20. This will make the thrust in the connecting rod, or total pressure on the crank pin greater than the total pressure on the piston.

To some this will seem a paradox, but that is what paradoxes are for. It appears to me that the mistake (if there is one) in the January and February numbers consists in calculating the thrust in the connecting rod as the total pressure on the piston x cos. a, instead of total pressure on the piston x sec a, sec a being the reciprocal of cos. a. Some engineer will undoubtedly put me right if I am wrong.—R. McLaren.

Note :— Our correspondent's claim is that the force on the connecting rod is greater than that on the piston. Without going into any further explanation of a subject which has been well gone into, we might say that if this were the case, it would be impossible for the piston to turn the crank at all. On the other hand the connecting rod would push the piston back against the force of the steam in the cylinder.

We should be glad to hear from some of our readers who may be able to convince Mr. McLaren.

INJECTOR OR PUMP

Question:— Why are injectors not the most economical boiler feeder there is, considering that all the heat in the steam used is returned to the boiler, while a pump wastes it in exhaust?

Answer:— Considered purely from a thermal or heat point of view, the injector is highly efficient. Its efficiency as a pump is however very low. Further the pump can feed water that has been heated by exhaust steam that would otherwise have been wasted, while the injector can handle only cold or moderately warm water. The duty of an injector, which is reckoned by the foot pounds of work done per million heat units is only about half that of the ordinary feed pump, while compared to high grade pumping engines it is much less.

STEAM IN PUMP CYLINDER

Question:— In a duplex pump feeding a boiler, is there steam in the cylinder at boiler pressure all the time? That is, does the steam remain at full pressure even after the stroke is finished until the other side has almost finished its stroke?

Answer:— The articles on "Overhauling and Adjusting In the Engine Room" contain information on this subject. However, we will explain the matter here for the benefit of those who have not read the articles. The steam is opened on the right hand cylinder by the left hand plunger moving forward. As the left hand plunger moves forward it gradually opens the right hand valve to give steam until it is full open to steam and open to exhaust on the back of the piston. The left hand rod will reach the end of its stroke before the right hand rod, and as the left hand valve is operated by the right hand rod, boiler pressure will be maintained on the left hand piston until the right hand piston has travelled past half stroke, when the left hand valve will begin to move over to give steam at the back of the left hand piston to make the return stroke, and the front end will be open to exhaust. There will thus be a slight pause between the rod reaching the end of the stroke and its start on the return stroke, during which time the full boiler pressure will be maintained. If the pump is working slowly this can be plainly seen, but of course is not so noticeable when the pump is working fast.

A STOKER QUERY

Question:— Will some of the many readers of Power House tell me the cause of stoker rods in Jones underfeed stokers burning off. We have a battery of four boilers equipped with Jones stokers, and the rods burn off frequently. The forced draught comes in at the back end of the retort.

Answer:— This condition does not occur in the newer types of Jones stoker, but was occasionally found in the older types. The trouble is in the burning out of the back of the retort, allowing the hot coals and ash to reach the rod. This can be prevented by building up the back of the retort where the rod passes through with firebrick or high temperature cement, thus preventing the burning of the back plates and rod.

A COMBUSTION QUESTION

Question:— Will you explain fully why it is more economical to have quick combustion than medium? If a ton of coal burned in a furnace for ten hours, generating a steady temperature of 1400 degrees Fahrenheit, would it be equal to a ton of coal burned in five hours at a temperature of 2800 degrees? Which will burn to the best advantage and evaporate the most water to a ton of coal? Are there any cheap and reliable instruments for observing and recording combustion conditions?

Answer.— One ton of coal contains a definite amount of heat units, and can only give up that amount. The efficiency of the combustion will depend entirely on whether the correct amount of air is admitted to mix with the coal, and if this condition obtains the rate of combustion will not matter. However, in practice it is found that when combustion takes place rapidly, a better mixture of air and carbon takes place, with a resulting higher temperature, and increased efficiency. It must be remembered that in steam generation the object is to get a high temperature in the furnace to transmit the heat rapidly to the water in order to evaporate it. The temperature of the flue gases will depend on the amount of air admitted to the furnace, and the efficiency of the heating surfaces of the boiler.You cannot take the difference of the furnace temperature and flue gas temperature, and call that the effective temperature. The efficiency will depend on whether the loss of heat between the furnace and the flue gases is caused by the boiler taking up heat from the gases or whether they have been cooled by air entering the setting between furnace and flue. You might have first class combustion conditions in the furnace, and through bad baffling or leaks in the setting have the gases either going straight out to the flue giving up very little heat, or on the other hand air leaking in the setting cooling the gases down and producing a low flue temperature. The advantage of a CO_2 instrument is beyond question, whether the boiler is on a heating system or otherwise. Consult advertisements for suitable instrument.

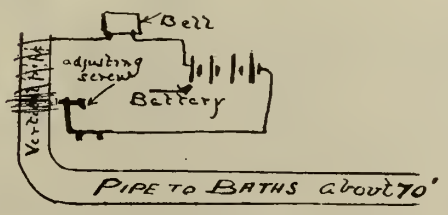
HEATING BUILDING

Question:— I have some trouble in heating the north and west rooms in a three story block, having a one pipe system, carrying seven pounds per sq. inch in cold weather. The main steam pipe comes from the boiler to the S. E. corner of the basement, and is reduced to 3 inches by a T, one branch leading across the south side of the building, and the other running along the east side to the north, where it crosses over to the west and back along the west side to the south again. Thus there is a three inch pipe supplying the south side of the building, and a three inch pipe supplying the other three sides. The drips are all collected at the southwest corner of the block, and returned to the boiler. What should be done to remedy this trouble?

Answer.— You have a five- inch pipe, which has an area neglecting fractions of 25 square inches. From this are taken two three inch pipes the combined area of which is only 18 square inches. Thus you have only 18 square inches to carry the supply coming from 25 square inches The pipe leading from the T to the north and west side of the building should be four inches instead of three which would give it an area of 16 square inches against nine square inches for the south side. This is nearly double, and would make an improvement. It would be cheaper to do as you suggest and put in a two inch pipe on the south side, but you would be reducing the capacity of the whole building. It is better to have free and unrestricted pipes, and if the larger main is used for the larger portion of the building, there will be better results. You would not need to carry the large main right around the building, but reduce it as the number of radiators or coils get less. For instance you might have it four inches long the east side, three inches along the north and two inches along the west. This of course is only approximate, and should be regulated by the amount of heating surface to be supplied.

CURING A HOT WATER TROUBLE

We had a great deal of trouble in the plant I am in, with the hot water system. The hot water is used for laundry and bathing purposes, and it was sometimes beyond the capacity of the system to supply the sudden demand. There was therefore an installation of two tanks, one of which was supposed to act as a storage for hot water, while the other was connected to the heater, and as the supply would go down in the storage the water in the tank connected to the heater would be warming up ready to change over. However as there was no way of telling when this reserve supply had been drawn off we often got caught by a sudden demand with the reserve tank cold. I noticed that the long supply pipe going from the tanks to the bath would contract about half an inch of its length when the water got cold, and from this fact I was able to rig up an alarm that would always give us warning when the water was getting cold. I connected up a battery and bell as follows. From the battery to one terminal of the bell, and from the other terminal of the bell to the water pipe taking a few turns



round the pipe with wire. From the other connection of the battery a wire was taken to a piece of flexible angle metal, and a screw was fitted in this to make the gap adjustable. When the pipe contracted due to cold water a connection was made with the angle, and the bell would ring. Very simple, but did the trick, and has never failed to work since it was installed.

WASHING DOWN BOILERS

I was interested in reading Mr. McLaren's article on the subject of blowing down boilers, and agree with him when he says that the proper time to blow down boilers is when the fires are active. I have had this proven to my satisfaction by observing the boiler emptying with fires out and no pressure on, at which time I have noticed that as the water leaves the tubes it does not remove the mud and sediment resting on them I have also noticed that the water leaving the blow-down was practically clean until the water reached nearly the bottom of the boiler.

I was told by an old engineer that the best way to empty the boiler is to wash it down as the water goes down in the boiler. thus removing the mud and sediment that is lodged on the tubes, and preventing it getting hard, especially when the boiler is still hot. I have tried this and found it work very satisfactorily. I also use a handy tool for scraping the scale off the tubes. It is made of three eighth inch dia. iron rod, one end being bent into a ring for the hand and the other bent to the radius of the tube. This can be pulled along the top of the tube scraping the scale off, and by reversing can be used to scrape the scale from the lower part of the tube.— G. D. B.

HORSE POWER FOR MOTORS

Question

What power would be required at the engine to drive a small manufacturing plant, having the following motors installed, and requiring 50 H.P. for the lighting load?

3 motors 16 H.P. efficiency of....82%
1 motor 20 H.P. efficiency of....85
2 motors 30 H.P. efficiency of 88
1 motor 9 H.P. efficiency of....80
1 motor 3 H.P. efficiency of....72

Please give horse power required if engine is direct connected, or belt connection is used.

Answer:

			Efficiency of Motor
3 motors	16	H.P.	.....82% = 55 H.P.
1 motor	20	H.P.	.....85% = 23.5
2 motors	30	H.P.	.....88% = 68.2
1 motor	9	H.P.	.....80% = 11.2
1 motor	3	H.P.	.....72% = 4.2
Lighting			50

215.6 H. P.

required to be delivered at the end of the cables supplying motors assuming the loss in conductors as 3 per cent, we get

215.6

$$\frac{}{.97} = 223.3 \text{ H. P.}$$

required at terminals of dynamo assuming efficiency of dynamo to be 93 per cent, we get

$$\frac{223.3}{.93} = 240.1 \text{ H. P.}$$

required at dynamo shaft.

If direct coupled, say efficiency of engine = 90 per cent, then

$$\frac{240.1}{90} = 266.8$$

If belt driven, say efficiency of engine and belt equal 85 per cent, then

$$\frac{240.1}{85} = 282.5 \text{ H. P.}$$

Direct driven, say 270 H.P. in engine cylinder; belt driven, 285 H.P. in engine cylinder

Useful work = 140 in motors + 50 in lamps= 190.

$$\frac{190}{270} = 70 \text{ per cent for direct driven.}$$

$$\frac{190}{285} = 66 \text{ per cent for belt driven}$$

ERRATA

An unfortunate error occurred in the issue of July 5th in the advertisement of the Diamond Specialty Co. The firm name appeared as the "Diamond Power Specialty Co.," whereas the word "Power" should have been omitted.

TORONTO NO. 1 LODGE C.A.S.E.

Toronto No. 1 Lodge C. A. S. E. is holding a picnic on July 30th on the Exhibition Grounds, Toronto, and a big day is looked forward to. The ground chosen is very suitable and convenient for a picnic, and the go-ahead members of this live lodge may be depended upon to make it a hummer.

LONDON LODGE C.A.S.E.

London Lodge C.A.S.E. held a very enjoyable picnic at Springbank on July 9, when a number of sporting events were run off. We had not the pleasure of being there, but the name of George Moll on the programme as chairman of committee assures us that there was nothing left undone to make it a success. There were in all 16 events, including some for all present, babies, boys and girls, married ladies, single ladies, benedicts and bachelors, and we believe all concerned had a great time.

SAVING WORN MACHINERY BY NICKEL

The high cost of iron and steel has stimulated engineers to develop efficient means of restoring parts which have become so worn that they are fit only for the scrap heap. A typical example is an engine crank shaft, which after a certain degree of wear, gets out of line to such an extent that it is useless. Welding has been largely used in the work of restoration, fresh iron or steel being welded on to the worn parts, and the whole then made true in a lathe. There are objections to this process in certain cases, and in order to overcome these objections a British engineer has developed a method of depositing nickel on the worn parts. The piece of machinery to be treated is first made free from grease and dipped bodily into a bath of molten wax. After the wax has cooled it is removed from the parts which have to be restored and is left on the others as a protective covering. Cleaning in a bath of acid is followed by immersion in an electro-plating bath which deposits nickel on the exposed surfaces. The coating of nickel is extremely hard, and when the process is properly carried out the nickel adheres with remarkable tenacity to the metal on which it has been deposited. Crank shafts, spindles, axles, pistons and similar objects can be made quite serviceable again by the nickel layer at a cost below that of replacing the whole part. Deposits up to one-eighth of an inch can be applied successfully. It is expected that this process will be developed alongside the welding process which British engineers have brought to so high a pitch of usefulness in many repairs, such as the mending of cracked or broken castings, which could not be handled by the deposition of nickel.

X-RAYS FOR FITTING BOOTS

Judging by the number of people who suffer from corns, bunions, flat feet and kindred troubles, the art of fitting boots is largely in need of scientific assistance. This assistance is now being given in Great Britain by means of X-rays. A simple, self-contained X-ray apparatus has been produced by which the customer and the shop assistant can see, on a fluorescent screen, the bones of the foot. The picture thus given shows exactly the real structure of the foot, from which an intelligent shop man can gauge the type of shoe which will give the customer the support and comfort he, or she, desires. The electric power required is so small and the exposure of such brief duration that there is absolutely no fear of any burning or ill effects from the use of this appliance.

A HARBOUR CUT OUT OF SOLID ROCK

There is a natural impression that all constructional engineering work of the ordinary kind in Great Britain was suspended during the war, but in point of fact it was found possible to keep quite a number of schemes going in spite of the concentration of effort upon definite war work. A case in point is supplied by an extensive harbour improvement which was begun in Great Britain a month or two before the war. The scheme included a new basin with an area of 2¼ acres and 1500 feet of new quays. All through the war the work proceeded steadily, if slowly. Its most remarkable feature was that the basin was cut out of solid rock to give an average depth of 13 feet. The material excavated was ingeniously used to reclaim from the sea a considerable tract close to the harbour.

"CARRYING ON" IN SPITE OF NO COAL

It is universally recognised that British engineers display their highest qualities in most serious emergencies, and this fact was amply proved during the recent prolonged coal stoppage. The electricity supply stations kept going by means of rapidly installed oil burners, and the gas works maintained an uninterrupted supply for a far longer period than was thought possible, by means of utilising their stores of coke in the production of water gas. Another interesting development of a more homely character was the institution, in Birmingham, of central supplies of hot water. These supplies were instituted for the benefit of the poor, who needed all their exiguous provision of coal for cooking purposes.

Speaking on acetylene gas as a lighting medium, the Daily Telegraph, Sheffield, England, states as follows: For country houses, the acetylene gas plant is simpler and more easily worked than the usual dynamo and accumulator; a layer of coke was put into each half core mainly to save good core sand and to keep the cores as light as possible, a little time in drying being also saved on this account.

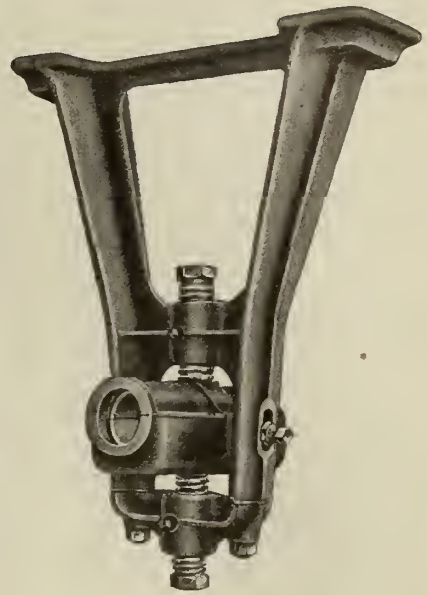
No special analysis was called for, the regular ten per cent. charge of semi-steel approximately 2.15 silicon, as used in the mixed class of work turned out by this company, serving the purpose admirably.

Owing to the fact that the company decided to grind the flange faces instead of machining, careful core jointing was necessary, three thirty seconds stock only being added to each flange face as finishing allowance.

The Philip Gies Foundry, Kitchener, have gone into the manufacture of specialities, among them being the Superior shaking and dumping grate bars. These can be adapted to any style of boiler.

The University of Illinois Engineering Experiment Station have issued Bulletin No. 120, which is the third in a series on warm air furnace research. This research into warm air furnaces and heating systems is being conducted in cooperation with the National Warm-Air Heating and Ventilating Association. This research should have far reaching effects both from a coal economy standpoint and a comfort standpoint, for there is no doubt that the average heating arrangements in houses on this Continent leave much to be desired from both these angles.

For Your Transmission



Oneida Steel Split Pulleys are both strong and light in weight. The smooth, grooveless, oval crown provides an ideal surface for belt contact. Oneida Pulleys will transmit power under low belt tension which means less power loss.

Universal Giant Hangers are standard equipment. Regular weight and perfect castings fitted with large plunger screws ensure perfect alignment. These hangers have universal adjustment and can be fitted with either Ring Oiling or Hyatt Roller Bearings.

Fairbanks Wood Split Pulleys embody many excellent features. All material is passed through two kiln drying processes. The web, which is mortised into the arms and rim, holds the whole pulley securely together.

Our nearest Sales Office will gladly furnish any information you may need.

LOCOMOTIVE BOILER MUD HOLES.

By H. BAILES.

Anyone familiar with the present method of gauging these mud holes with a plate knows that this system is inaccurate. First of all, dirt and rust adhere to the threads, and secondly, the plate only measures the bottom of thread on plug. In the rush of making a speed "test out," quite frequently the taps are not put in these holes to clean out or straighten up the threads, with the result that many plugs are blowing steam when the engine ought to be leaving the shops.

After tapping all the holes in a boiler, the writer has used with good success a set of old plugs for the purpose of gauging the size of these holes. The plugs are from 1⅞″ diameter to 2½″ diameter, these increasing by 1-16″, this making eleven plugs to the set. The size of the plug is determined by calipering the fourth thread from the end, i.e. ⅜″ from the end, or the width of a pair of outside thread calipers.

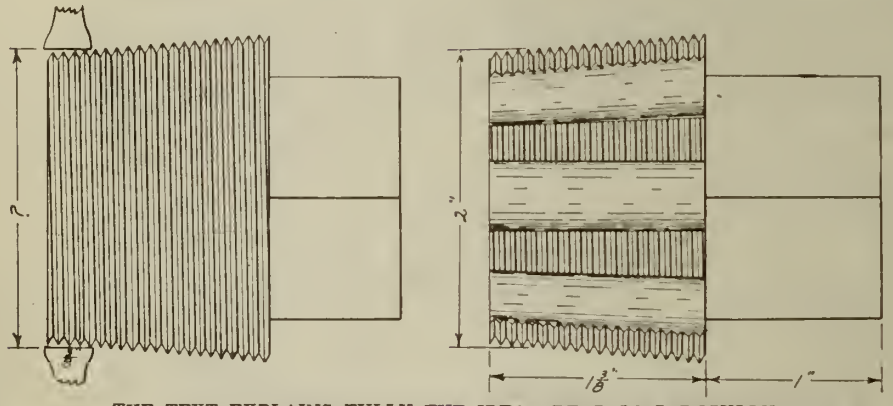
Each plug is stamped on top as follows: 1-7, 1-15, 0, 1, 2, 3, 4, 5, 6, 7, 8; 0=2″ diameter, and the whole numbers above this signify 1-16″ increase in diameter. No. 3 represents 2 3-16″ diameter; No. 4, 2¼″ diameter, and so on. Below the cipher No. 1-7=1⅞″ diameter; 1-15 1 15-16″ diameter. In use, the practice is to chalk above each hole the number of the plug used. Thus, the abbreviated method of marking comes in very handy.

In some cases a plug may enter three or four threads only. For example, suppose this happened with a number four, or 2¼″ diameter plug. A No. 3 plug would enter this same hole to within four or five threads of the top. What would be the size to take? In such an instance, the mean diameter or 2 7-32″ would be correct, the hole to be marked 34, signifying the diameter as being the mean of these two sizes. Thus, 56 would equal 2 11-32″; 1-31 = 1 31-32″, etc. From past experience, I found these sizes comprise the standards excepting inspection holes and one or two isolated cases, viz.: 1⅝″, 1¾″, and 1 13-16″ diameter, which may be determined by inside thread calipers.

Now, substitute taps for the plugs, i.e., plugs duplicated in hardened steel, and milled with teeth for cutting purposes. The mud holes of many boilers vary from three to four sizes, so it is merely a question of measuring one hole with your scale and securing one or two plug taps above or below the size measured. By this method you are sure to use the taps, and besides, these taps are more effective, to my mind, in tapping new holes than the usual long standard tap.

The method of using old plugs is also expensive and inaccurate, the process being to anneal them before sending to the lathe. The lathe hand has plate sizes for one set and proceeds to chase the threads up with a hand chaser. In many cases the plugs are returned with a taper which does not correspond to the hole. In conclusion, I would suggest a set of adjustable dies, graduated similar to the plug taps, of the same taper and pitch, so that the old annealed plugs could be rethreaded by unskilled labor, using an old drill head.

Hollow concrete piles are being made by a novel process in Los Angeles, according to the Engineering News Record. They range from 42 feet to 60 feet long by 18 inches to 20 inches outside diameter, with a thickness of about 4 inches. A solid point of reinforced concrete is made and stood on end in a high scaffold. Paper cylinders representing the internal diameter of the pile are then erected above the point and the reinforcement put in place. Cement-granite concrete is then applied by means of a cement gun, in stages of about 6 feet high. After standing from eleven to fifteen days the piles are picked up by a locomotive crane and leaned against a rack to season for thirty days. They are then transferred, still in the vertical position, to a rack on a barge for conveyance to the works. By these means it is hoped to avoid the cracking sometimes caused by upending piles cast horizontally.



THE TEXT EXPLAINS FULLY THE IDEA. READ IT CAREFULLY.

NEW TYPE INDICATING PRESSURE GAUGE

The "Gasmaker's" gauge, a recent development of the Schaeffer & Budenberg Mfg. Co., of Brooklyn, N.Y., fills a long felt want of the gas industry. The tendency to increased production in gas plants puts bigger loads and consequently higher pressures on every piece of gas works apparatus. It is very difficult to successfully use water gauges in the measurement of pressures much over 36 in. and this has led to the development of this new type gauge. Furthermore, glass column gauges are extremely fragile and hard to read.

The gauge shown is very substantially constructed and will stand any kind of abuse. Continuously fluctuating pressures such as produced on a generating set or at the outlet of an exhauster have absolutely no detrimental effect upon it. The gauge is of simple construction with few moving parts and practically nothing to get out of order. The movement of a diaphragm of metal, specially selected so as to withstand the action of any gas (even chlorine gas) is transmitted to a pointer on a dial, which is calibrated in "inches head of water," for any desired range.

The gauges are adaptable to any service, such as on blast mains, generators, carburettors, superheaters, washboxes, condensers, tar extractors, purifiers, meters, or holder mains. In fact, wherever one desires to read pressures in inches head of water. They are also made for high or low pressure alarm service. An adjustable electrical contact point is placed on the dial and can be set to ring an alarm at any desired pressure. Should the pointer on the dial after long continuous service not return exactly to the zero position, an adjusting screw is provided for resetting. In fact, it is a universal gauge that can be constructed for use on any desired pressure or service.

Men in the manufacturing department of any gas company will immediately recognize the value of a gauge of this type.

DIESEL ENGINE PROGRESS.

Some time ago we described in these columns the Cammell Laird Fullager Diesel engine, which is of the opposed piston two-cycle type, and is also notable for the fact that the pistons in adjacent cylinders are connected by diagonal rods. The top piston of one cylinder is thus connected to the bottom piston of the adjoining one, and two cylinders and four pistons form a unit.

There is now being built a Cammell Laird Fullagar engine of 4000 B.H.P., which will be the largest unit yet built for marine work on the Diesel principle. This is a four-cylinder unit, and owing to the long stroke possible with this type of engine, the revolutions will only be 90 per minute, with a comparatively small cylinder diameter of 26 inches. The stroke of each piston is 42 inches. The comparison in weight and floor space is very much in favor of the two-cycle engine of the opposed piston type as against the four-cycle type of Diesel.

Trials recently made on the first 1000 B.H.P. unit built of this type gave a consumption per b.h.p. of only .39 lbs. fuel per hour.

SOMETHING NEW IN WINDMILLS

Many attempts have been made to solve the problem of efficiently utilizing the winds as a means of generating electricity. The difficulties arise from the extreme variations in the force of the wind and from the liability,even in windy regions, to periods of calm during which no power at all can be obtained. The conditions suggest that wind power should be used only as an auxiliary to some other source of energy, such as the burning of coal or oil. Now that fuel of all sorts has multiplied in price there is all the more reason for considering the possibility of turning the wind to account. Hitherto the usual plan has been to use a large slow-speed windmill to drive a dynamo at a high speed through gearing—a rather wasteful arrangement. During the war, however, there was in Great Britain a remarkable development in the design and construction of small high-speed dynamos on aeroplanes. These dynamos were direct-coupled to propellers or rather "impellers" driven by the wind created by the aeroplane in flight. A British firm has devised a scheme for fitting three or more of these wind-dynamos on the swivelling top of a vertical pole; with a vane to keep them in position against the wind. Each equipment gives 60 watts, and the arrangement forms a cheap and efficient auxiliary to the ordinary country-house lighting installation. The energy produced is, of course, stored in accumulators in the usual way. The operation of the plant is entirely automatic and it is so light and simple that it presents no obstacles in erection and maintenance.

A RAPID STONE-CUTTER

Machines for cutting marble and other stone have a pedigree stretching back to very early days in civilization and they still often bear the marks of their primitive ancestry. Recently, however, a British engineering firm introduced a type which more closely resembles a machine tool than the crude equipments with which our forefathers were content. It is intended mainly for cutting and moulding but it may be used also for slab and block work. The stone to be cut is placed on a table surmounted by a saddle carrying a carborundum wheel or a "diamond saw", which runs at 1,200 revolutions per minute and is kept cool by streams of water. A diamond saw is built up by arranging individual diamonds in metal "saddles" on the rim of a disc. Each saddle is drilled from behind, the diamond inserted in the hole and electrically welded over, and then mounted on the rim. The metal covering the diamond is ground away leaving the diamond exposed. Wheels of this type make very rapid and efficient cutters of stone and the use of the machine is expected to lead to remarkable economies over the older methods.

STETHOSCOPE IN WORKSHOPS

Most of us are, unfortunately, more or less familiar with the stethoscope, which the doctor uses when listening for the signs of defective action in our lungs or heart. It is not so widely known that the same kind of instrument can be employed to detect abnormal noises in moving machinery. The latest development in this workshop stethoscope, due to a British engineer, lies in the use of a kind of telephone receiver in place of the stethoscope rod. The advantage of this device is that every bearing and every gear in a factory can be fitted permanently with a receiver and all the receivers can be connected by electric wires to a single board in the manager's office or any other convenient spot. By means of suitable switches the manager can examine each bearing or gear in succession without moving from the board. Since abnormal internal noise is often the first sign of trouble which may lead to breakdown, this simple and rapid means of detection is an invaluable aid to the factory owner.

The Refinite Company of Canada has been incorporated into premises at 319 Continental Life Building, Toronto, and will manufacture the Booth Water Softening Systems and the Refinite Pressure Filters. "Refinite" is a natural water softening mineral, and the company controls the only known deposits on this continent, it is claimed. The Company will be under the management of Mr. E. G. Koyl, who is an experienced water engineer. Mr. Koyl is a veteran of the great war, having enlisted in the first McGill University Company at Saskatoon, in 1915. The company will be represented at Saskatoon and on the coast.

The Underfeed Stoker Co. are now making a simple coal crushing device which can be attached to an ordinary standard stoker. The crusher has been invented and developed by two users of of the Jones stoker, and has been in use for over a year with good results.This crusher is placed directly over the hopper of the stoker, and the rolls are operated through a ratchet and lever connected to the pushrod of the stoker. The crusher is arranged to be operated by the return stroke of the push rod, thus utilizing the excess of power which is available on this stroke. The coal is thus crushed just as it is used, and the power used by the ram on each stroke is equalized. The feature of the crusher which will appeal to every power plant operator, is its simplicity, the whole thing being self-contained.

--and who wants to waste steam at present prices of coal?

With coal costing as high as $13 a ton—and often hard to get at any price—it is far cheaper to put in enough Steam Traps Sarco to stop loss of steam through condensation than to stand the alternative of big waste at the coal pile.

Steam Trap Sarco puts the whole question of proper trapping vs. waste of coal on an entirely new basis—

It pays for itself at points where a Big Trap wouldn't Be Justified.

You can put in three Sarcos for the cost of just one bucket or floor trap—thus for the same expenditure saving three times as much steam and therefore three times as much coal. Because it costs only one-third as much, a Sarco will quickly pay for itself at points where the expense of an old-style trap wouldn't be justified.

Sarco is more dependable and efficient than old-style traps. It operates automatically—on a simple yet extremely sensitive and responsive system of liquid expansion and contraction. So positive in action that not an ounce of live steam can escape from one year's end to the other.

Drains off all condensate as fast as it forms—and immediately returns it to the hot well—while still hot, thus requiring less coal to convert it back into steam. And never any water (condensate) left in the pipes to freeze overnight or over Sunday.

30 DAYS' TRIAL.

We are ready to let Sarco demonstrate its superiority and economy right in your own plant by sending you one on 30 days' free trial without a cent in advance. If for any reason you aren't satisfied with its performance, you can return it and it won't cost you a cent.

Made in sizes ⅜ in. to 3 in. for any given pressure up to 200 pounds.

Booklet No. J-12 and full particulars about our free trial on request.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract. Readers are requested to advise the publishers regarding any equipment that they are buying and that is not listed.

Protect Your Plant

By installing Evans' "ALMETL" Firedoors in your plant, you entirely eliminate the danger of fire spreading. They afford the best protection that money can buy or brains devise.

"ALMETL" Firedoors are built of steel, heavily galvanized—there are no wood cores "protected" by light terne or similar covering. The "ALMETL" is absolutely guaranteed not to sag, twist or warp, and will withstand the most intense fire. There's not a bolt used in its construction—all joints are RIVETED. The interlining of asbestos rollboard is a special feature.

Our Department "A" will gladly furnish drawings and details of the "ALMETL."

Geo. W. Reed & Co., Limited

MONTREAL

MADE IN CANADA

DARLING PATENTED FIRE HYDRANT

Flanged connection to hydrant base permits pointing the nozzle in any direction. Bottom of base comes on level with water main and does not require excavation below main.

DARLING PATENTED GATE VALVE

The large valves that are operated in a horizontal position require no auxiliary mechanism for carrying the internal parts. The discs themselves roll like two wheels and carry the wedges.

MONCRIEFF'S

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is economical. British Made.

"UNIFIC" WATER GAUGE

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

GLASSES

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

Canadian Representative: W. J. WALL, 134-136 Bleury St., MONTREAL, CANADA

Chimney Repair Work

Does your chimney need repairing? Experienced chimney foreman and expert repair man is open for engagements. Put your problems up to me. Rates reasonable.
Box 203, Power House.

EQUIPMENT

WE BUY IDLE EQUIPMENT OR MACHinery; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

SITUATIONS WANTED—MALE

STATIONARY ENGINEER (2ND CLASS)—would appreciate steady position in country; references A1. Apply, mentioning Power House, to Box 218, Globe.

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House.

READER'S NOTICE

Regarding

CHANGE OF ADDRESS

A REQUEST FOR CHANGE OF ADDRESS must reach us at least thirty days before the date of the issue with which it is to take effect. Duplicate copies cannot be sent to replace those undelivered through failure to send this advance notice. Be sure to give your old address as well as the new one.

CITY OF EDMONTON

MACHINERY For Sale

The City of Edmonton has for sale one complete Generating Unit, consisting of One Goldie McCulloch Cross Compound Corliss Engine 25" x 50" x 36 operating at 120 R.P.M. and 160 lbs. per square inch steam pressure direct coupled to One General Electric Generator Type A. T. B. 60 cycle 1,000 K.W., 2,300 volts, 251 amps.

TENDERS TO BE ADDRESSED TO THE CITY COMMISSIONERS,

301 CIVIC BLOCK,
EDMONTON, ALTA.

ELECTRIC MOTORS—NEW AND SECOND-hand; electric machinery repaired; we also buy motors. Apply, mentioning Power House, The Electrical Engineering Co., 122 Wellington West, Toronto.

SAWMILL MACHINERY MANUFACTURED by sawmill machinery specialists. Apply, mentioning Power House, The E. Long Manufacturing Co., Limited, Orillia.

FOR SALE—ONE 16-INCH, ONE 24-INCH Sheldon exhaust fans, practically new. Apply, Box 205, Power House.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House, H. W. Petrie, Limited, Toronto.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

FOR SALE

1 H.R.T. BOILER—72-IN. x 16-FT. SHAKER grates and stack, complete; 125 lbs.
1 H.R.T. BOILER—60-IN. x 14-FT., 120 pounds. Apply, mentioning Power House to Wilson-McGovern, Ltd., Lumsden Bldg. Toronto.

THE JOHN INGLIS CO., LTD., ENGINeers and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention Power House.

THE MILNES COAL CO., LTD., 85 KING St. East, Toronto; soft coal (any grade) hard coal, any size, in carlots. Write for prices, mentioning Power House.

STEAM ENGINES, BOILERS, HEATERS, tanks, stacks, pumps and condensers, transmission and elevating machinery, safes, vaults and vault doors; catalogue and specifications sent on request. Apply, mentioning "Power House," to Goldie & McCulloch Co., Ltd., Galt, Ont. (pfh)

LIGHTING PLANT FOR SALE—1200 UNit Lalley light farm-lighting plant; new; complete with Willard storage batteries, 32 volt; suitable for summer home; lighting at half price; for immediate cash sale, $400. Apply, mentioning Power House, Smith & McLaughlin, 259 Colborne St., Brantford, Ont.

FOR SALE—A NUMBER OF SECOND-HAND machine tools in excellent condition; these may be inspected at our works. Apply, mentiontioning Power House, The Waterous Engine Works, Co., Limited, Brantford, Ont.

PLIBRICO JOINTLESS

FURNACE LINING

After being molded into shape and properly baked and vitrified PLIBRICO makes front-door arches, side walls, bridge walls, and baffles that are air tight and gas tight. No leaks to retard combustion and thus eat into the coal pile—and the pocketbook. Any man can apply it. No forms needed. Excellent also for patching.

PLIBRICO is delivered only in steel containers of distinctive appearance as shown below.

JOINTLESS FIRE BRICK CO.

1142 CLAY ST., CHICAGO, ILL.

DISTRIBUTORS:—Beveridge Supply Co., Ltd., Montreal, Que.; Shell Bar Boico Supply Co., Ltd., Toronto, Ont.; Evans, Coleman & Evans, Vancouver, B.C., Winnipeg Supply & Fuel Co., Winnipeg, Man.; Gorman, Clancey & Grindley, Calgary, Alta.

How to Test Advertising

THE man who doubts the power of advertising belongs in the same class with the man who refuses to believe that the world is round simply because he can't get off somewhere at a distance and see its roundness for himself.

The merchant who fears to attempt advertising because he figures it as an "expense" is blind to his own interests. I personally know several men who, because they once tried advertising to the extent of a cheaply printed hand-bill and didn't find it necessary next morning to call on the police to keep the crowds of eager buyers from swamping their store, loudly and solemnly aver that "advertising doesn't pay."

Advertising *does* pay.

The most successful merchants are the merchants who believe most thoroughly in advertising and who practice their belief.

But advertising, in order to pay, has got to be *intelligent* advertising.

The day of hashed-over superlatives — "best goods," "lowest prices," "best stock in town," "greatest bargains ever heard of," and so on—has passed.

People have learned to distinguish the *truthful* advertiser from the blatant behind-the-times storekeeper who believes that, so long as *he* claims to have the best goods on earth, or under the earth, or within wireless distance of the earth, people will break their necks trying to get to his counters in the forefront of the crowd.

Put some *brains* into your advertising.

Don't let the office boy write your announcements in between his other duties.

Don't doubt the business-getting and business-building power of intelligent and informative publicity — and you will find that advertising *does* pay.

—*Jerome P. Fleishman.*
